CHAPTER 1

INTRODUCTION

1. Purpose

This manual provides guidance to commanders, staffs, and intelligence personnel concerned with the collection, processing, and use of intelligence information gained by aerial means. It sets forth doctrine, tactics, and techniques for the planning, coordination, and employment of all aerial surveillance and reconnaissance resources.

2. Scope

a. This manual outlines the procedures for determining aerial surveillance and reconnaissance requirements, for requesting aerial reconnaissance and surveillance support, and for planning and coordination incident to the collection of aerial reconnaissance and surveillance information. It also discusses organizational and operational aspects of both the Army and other services' aerial surveillance and reconnaissance community. This manual includes only those details and techniques described in other manuals which are necessary for complete understanding and continuity.

b. Only the mechanical aspects of processing and disseminating the information obtained by aerial means are discussed in this manual. The evaluation, interpretation, and use of the product resulting from the employment of aerial surveillance and reconnaissance collection means are discussed in FM 30-5.

c. The technical aspects of the equipment used in aerial surveillance and reconnaissance and the procedures utilized by aerial surveillance and reconnaissance specialists in the performance of their duties are not discussed in any great detail in this manual. This information is contained in appropriate technical manuals and other published media available to the specialists and technicians

responsible for the employment of the equipment and procedures.

d. The material in this manual is applicable to nuclear and nonnuclear warfare, and internal defense/development operations under all conditions, including the employment of chemical, biological, and radiological agents.

e. Within this manual, all discussion pertaining to the duties, functions, and responsibilities of the G2 or G2 Air will apply equally to the S2 or S2 Air in organizations below division level, unless otherwise stated.

f. Within this manual, aerial surveillance and aerial reconnaissance are not treated as mutually exclusive intelligence gathering activities. When the term aerial surveillance or aerial reconnaissance is used separately, it is intended to convey which of the two activities will receive the major emphasis; however, it should not be construed as excluding the other activity, unless otherwise stated.

g. Guidance established by STANAG No. 2029, 2102, 3189, 3277, and 3377 has been incorporated into appropriate chapters and/or appendixes to this manual.

h. Users of this manual are encouraged to submit recommendations to improve its clarity or accuracy. Comments should be keyed to the specific page, paragraph, and line of the text in which the change is recommended. Reasons should be provided for each comment to insure understanding and complete evaluation. Comments should be forwarded direct to the Commanding Officer, U.S. Army Combat Developments Command Intelligence Agency, Fort Holabird, Md. 21219. Originators of proposed changes which would constitute a significant modification of approved Army doctrine may send an information copy, through command

channels, to the CG, USACDC, to facilitate review and followup.

3. Responsibilities

a. Each commander is responsible for the intelligence activities of his command as defined in FM 100-5. To accomplish these activities he delegates the functions of intelligence planning, coordination, and production to his principal staff assistant for intelligence—his G2 or S2.

b. In the accomplishment of his staff responsibilities for all intelligence functions, the G2/S2 must properly plan, employ, and control or coordinate the aerial surveillance and reconnaissance capabilities at hand or available to meet his requirements. At brigade level or lower, these are functions of the S2 or assistant S2. At division level and above, these functions are performed for the G2 by his principal assistant for aerial surveillance and reconnaissance operations—the G2 Air. A detailed discussion of the G2 Air organization and function is contained in chapter 2.

4. Means of Collection and Processing

a. Collection Means.

- (1) Organic Army aerial collection means include airplanes, helicopters, pilots, aerial observers, sensors, and sensor equipment operators which can collect information from aerial platforms out to the operational limits of the aircraft or sensors. Present collection capabilities include visual observation, photography, radar, infrared imagery, and electronic surveillance.
- (2) Other services, principally the Air Force but also the Navy and Marine Corps, when included as part of a joint operation, provide the aerial collection means required to increase the area of coverage capabilities of the Army, and also extend that coverage beyond the limits of organic Army aerial collection means. Present

collection capabilities include visual observation, photography, radar and infrared imagery, radar mapping, electronic reconnaissance, and weather reconnaissance.

b. Collection and Processing Agencies.

- (1) The Aerial Surveillance Company is a specialized organization containing Army aircraft, sensors, data terminals, and the necessary technicians to collect, interpret, and disseminate intelligence information from aerial imagery. The company provides the Army with an organic means of procuring intelligence information in immediate response to the commander's needs. A detailed discussion of this organization is contained in chapter 8.
- (2) The Military Intelligence Battalion, Air Reconnaissance Support, Field Army (MIBARS), is a specialized organization created to provide the Army an organic means of interpreting, processing, and disseminating intelligence information from aerial reconnaissance missions flown by the Air Force or other services in support of the Army's requirements. It also provides liaison officers to the reconnaissance elements of the supporting tactical Air Force. A detailed discussion of this organization is contained in chapter 7.
- (3) Contained within the military intelligence organization supporting the field army, corps, division, separate brigade, and armored cavalry regiment are imagery interpretation (II) sections that directly support their respective headquarters G2 or S2 staff section. This II support is immediately responsive to the commander's needs and can provide all II functions. A detailed discussion of II functions is contained in chapter 9.

CHAPTER 2

G2 AIR ORGANIZATION AND FUNCTIONS

Section I. ORGANIZATION

5. General

a. The planning and coordination of aerial surveillance and reconnaissance operations of the command are the staff responsibilities of the ACoF, G2, or of the S2 below division level.

b. At division and higher echelons, the G2 Air is responsible to the G2 for supervising the collection and dissemination of information concerning the location, strength, disposition, movement, and military installations of the enemy as visually observed and sensed from the air; and to advise the G2 on matters pertaining to aerial surveillance and reconnaissance employment. To accomplish these responsibilities, he formulates policies and procedures for use in selecting missions; exercises staff supervision over organic Army aerial surveillance and reconnaissance agencies; requests aerial surveillance and reconnaissance support from other services; receives, consolidates, and assigns priorities to aerial surveillance and reconnaissance requests; disseminates intelligence reports resulting from aerial surveillance and reconnaissance missions; and performs necessary staff coordination.

6. Location and Organization

a. *General.* G2 Air personnel are located at all command echelons from field army through division. At echelons below division, G2 Air functions are performed by the S2 or his assistant when provided. As an exception separate armored, infantry, and mechanized brigades have organic S2 Air personnel.

b. *Location.* The Tactical Air Support Ele-

ment (TASE) of the Tactical Operations Center (TOC) at field army, corps, and division levels consists of collocated G2 Air duty teams and G3 Air representatives. The TASE normally is located with the Fire Support Coordination Element (FSCE) which is also part of the TOC. Though collocated, the G2 Air, G3 Air, and FSCE elements are not combined, but each remains under the direct control and authority of its own team chief and its respective general or special staff officer.

c. *Organization.* The G2 Air sections at field army, corps, and division are organized into duty teams to provide 24-hour operation. Actual composition of each duty team is at the discretion of the G2 Air; however, at field army level it is desirable that a long-range planning section and a duty team for the alternate Field Army Tactical Operations Center (FATOC) be organized.

d. *Personnel Augmentation.* Personnel authorized for G2 Air sections at all levels are the minimum required for operational efficiency, and additional personnel may be required for extended operations. This is especially true when the G2 Air has staff supervision over organic Army aircraft; this will require the normal employment of a G2 Air representative with the flying unit as a liaison officer and briefer-debriefer.

e. *Independent Operations.* When organic divisional brigades are assigned to independent operations for prolonged periods of time, provision should be made for inclusion of an S2 Air to augment the brigade S2 staff.

Section II. FUNCTIONS

7. General Functions

General functions of the G2/S2 Air at all echelons include the following:

a. Advises the G2/S2 on matters pertaining to aerial surveillance and reconnaissance.

b. Recommends policies and procedures for the conduct of aerial surveillance and reconnaissance.

c. Prepares the aerial surveillance and reconnaissance SOP.

d. Prepares the aerial surveillance and reconnaissance plan.

e. Assists other staff sections in establishing aerial surveillance and reconnaissance requirements to include special studies.

f. Processes aerial surveillance and reconnaissance requests; approves or disapproves requests from subordinate elements and the staff at his own echelon.

g. Establishes a priority system for aerial surveillance and reconnaissance requests and monitors all priorities assigned to requests submitted within the command.

h. Maintains and disseminates information on the capabilities and allocations of the aerial surveillance and reconnaissance support.

i. Disseminates information resulting from aerial surveillance and reconnaissance operations.

j. Develops cover and deception measures to support aerial surveillance and reconnaissance operations.

k. Exercises staff supervision over Army aerial surveillance and reconnaissance elements organic to, or in direct support of, his command.

l. Coordinates with G3/S3 Air in the planning of close air support and interdiction, and aerial surveillance and reconnaissance missions.

m. Coordinates with the G3/S3 Air and the FSCE for necessary shifting or lifting of supporting fires that may interfere with the accomplishment of an aerial surveillance or reconnaissance mission.

n. Coordinates with the appropriate Air Force elements, those requests for immediate

aerial surveillance and reconnaissance missions to be accomplished by the Air Force.

o. Provides for briefing and debriefing personnel directly engaged in aerial surveillance and reconnaissance operations.

p. Supervises the imagery interpretation effort at his echelon.

8. Specific Functions

Additionally, the G2/S2 Air accomplishes specific functions relating to his level of assignment as follows:

a. *Field Army/Independent Corps G2 Air.*

(1) Coordinates the scheduling of available aerial surveillance and reconnaissance support with the Tactical Air Control Center (TACC), and with Navy, Marine, and organic Army aerial surveillance and reconnaissance units if provided to the command.

(2) Conducts appropriate portions of the daily planning conference with TACC, and with representatives for Navy, Marine, and organic Army support if provided.

(3) Supervises the employment of the Military Intelligence Battalion, Air Reconnaissance Support, Field Army (MIBARS).

(4) Disseminates intelligence concerning the enemy air defense capability to the TACC and other aerial surveillance and reconnaissance units, if provided; and intelligence concerning enemy air operations capabilities to the TOC.

(5) Insures the availability of current initial record imagery (basic cover) (para 26) of the field army area of interest, and dissemination of appropriate portions of the initial record coverage to subordinate units.

(6) Disseminates to the TACC and other flying units in support, to the MIBARS and to the field army G3 Air element at the TASE, intelligence reports on enemy ground activities.

b. Corps G2 Air.

- (1) Coordinates preplanned missions between division and field army G2 Air.
- (2) Approves or disapproves, and coordinates approved immediate aerial surveillance and reconnaissance requests with the Direct Air Support Center (DASC), or the Aerial Surveillance Company.
- (3) On approved immediate requests flown by the Air Force, insures that the MIBARS detachment, collocated with the AF reconnaissance squadron scheduled for the mission, receives the information required for briefing the flying crew and assisting the detachment's interpretation effort.
- (4) Exercises staff supervision over the corps Aerial Surveillance Company for the Corps G2.

c. Division G2 Air.

- (1) Monitors immediate aerial surveillance and reconnaissance requests of subordinate elements and indicates approval or disapproval to the divi-

sion Tactical Air Control Party (TACP).

- (2) Coordinates the employment of the corps Aerial Surveillance Company ground sensor terminals, located within the division area, with the operations of the imagery interpretation support available to the division.
- (3) Coordinates with the G3 on the utilization of organic or direct support nonreconnaissance aircraft of the division for visual missions of high priority that are within the capability of the aircraft to accomplish.
- (4) Integrates the command's aerial and ground surveillance and reconnaissance plans.
- (5) Exercises staff supervision over organic or attached Aerial Surveillance units when provided.

d. Separate Armored, Mechanized, and Infantry Brigades. The functions of the S2 Air for these commands are comparable to those accomplished by the division G2 Air.

CHAPTER 3

CONCEPT OF AERIAL SURVEILLANCE AND RECONNAISSANCE EMPLOYMENT

9. General

Aerial surveillance and reconnaissance missions are performed in support of the field army and its subordinate units by aviation units organic to the Army, the Tactical Air Force (TAF), or other supporting services. The TAF or air arm of other supporting services provides a large portion of the total aerial surveillance and reconnaissance effort required by the field army; however, whenever organic army means can more effectively or more responsively meet the requestor's needs, they should be used within the limitations of their aircraft and sensors. As specific surveillance or reconnaissance requirements are developed at any echelon, they are either accomplished with the means organic to that echelon or submitted to a higher headquarters for accomplishment.

10. Support by Tactical Air Force

Tactical air reconnaissance elements of the Air Force normally support both Army and Air Force intelligence requirements. Tactical air reconnaissance is one of the primary sources of intelligence information available to the Army commander for planning purposes and for support of immediate operational requirements. Tactical air reconnaissance units are capable of performing all missions within the entire spectrum of air reconnaissance, both day and night, and through most weather conditions. The Air Force normally provides a tactical air reconnaissance wing, consisting of four reconnaissance squadrons, in support of a field army. Normally, the reconnaissance wing will also have a reconnaissance technical squadron that has a photo processing and imagery interpretation capability. Usually, this capability is concentrated at the reconnaissance wing level; when required, however,

personnel and equipment from this squadron may be collocated with one or more of the reconnaissance squadrons to provide direct support. The reconnaissance squadrons usually operate from improved airfields dispersed throughout the theater of operations. Each squadron may be equipped to provide only a portion of the total reconnaissance capability; i.e., one may be a day squadron for visual and photographic reconnaissance, one a night squadron for infrared and radar reconnaissance, and one a weather-electronic reconnaissance squadron for the collection of weather data and enemy electronic order of battle. Conversely, each squadron may be equipped to perform all of these functions on a continuous basis, or may be equipped to provide a major capability in one area and a limited capability in another area. The composition and mix of reconnaissance squadrons is the responsibility of the senior Tactical Air Force commander.

11. Navy and Marine Corps Support

a. When Navy or Marine Corps air units provide the preponderance of air support to Army operations, operational procedures will be established by the joint force commander, but so far as possible, these procedures should follow general doctrine as presented in this manual.

b. Navy and Marine Corps air reconnaissance units possess the necessary aircraft and imagery producing sensors to accomplish the same types of missions as those performed by the Tactical Air Force. These units also have an organic capability for processing and interpreting imagery returns.

c. Depending upon operational requirements and the volume of support being provided, Navy and Marine Corps imagery may be delivered to the land airbases at which the

MIBARS detachments are located. In other instances, a portion of the MIBARS personnel, to include entire detachments, may be located aboard ship or at a Marine airbase to aid in processing and interpreting exposed imagery. If necessary, the MIBARS headquarters has the capability of creating a fifth MI Detachment (Air Reconnaissance Support) for special operations as discussed in chapter 7. In addition, a separate MI Detachment (ARS), not organically part of an existing MIBARS organization, can be created to fill a special requirement to operate with a Navy or Marine air reconnaissance unit at the same time that the existing MIBARS organization continues to function in support of a Tactical Air Force reconnaissance wing.

d. Navy and Marine Corps air reconnaissance units may require Army liaison officer support to be located with their flying elements. When required, liaison officers can be procured by using imagery interpretation officers out of the imagery interpretation sections within MIBARS or out of the imagery interpretation section organic to the military intelligence organization in support of the Army combat units.

12. Allied Support

When supported by aerial reconnaissance elements of allied nations, commanders concerned will use mutually acceptable procedures and techniques.

13. Army Aviation Support

Army aviation units of the armored cavalry regiment, missile command, division, corps, and field army are all capable of performing visual aerial surveillance missions. In addition, the Corps Aerial Surveillance Company and the aerial surveillance platoon organic to the airmobile division can provide permanent record imagery from photographic, radar, and infrared sensors.

14. Aerial Surveillance Intelligence Cycle

a. *General.* The aerial surveillance intelligence cycle (fig. 1) is based on the determination of a specific requirement for information and the action necessary to fulfill the requirement at any echelon of command. The G2 Air may initiate a requirement, or he may receive

it from another staff section or from a subordinate unit. As the G2 Air, he is the staff supervisor of the request until action upon it has been completed and the originator so advised. At each echelon, the G2 Air action sequence follows a similar pattern. Variations at each echelon involve personnel, equipment, and administrative detail, but the same thought process and sequence of action are used. Close staff supervision must be exercised through all phases of the cycle and coordination with supporting units must be effected by the G2 Air to obtain maximum return from the effort expended. Development of a specific unit SOP will facilitate and expedite the performance of these functions.

b. *Field Army and Independent Corps Aerial Surveillance Intelligence Cycle.* The G2 Air at field army level normally will perform as a staff supervisor and coordinator of the aerial surveillance and reconnaissance effort of the field army. Normally he will process only those requests which originate at field army level or which cannot be accomplished at corps level and below and are forwarded to field army for accomplishment.

- (1) *Air request control.* Requests received or originated at field army are approved by the G2 Air. Upon approval of each request, a priority is established. An approved request may be accomplished by organic means or forwarded to TAF (TACC). Close coordination between the G2 Air and TACC is necessary to determine the priority in which requests are accomplished by the Air Force. When the TACC designates a unit to fly the mission, the G2 Air is notified. The G2 Air then furnishes the MI Battalion (ARS) with the detailed mission information.
- (2) *Mission accomplishment.* Once the requirement is furnished the MI Battalion (ARS), the actions to coordinate, receive, and interpret the resultant imagery are the responsibility of the Army element even though the mission is flown by an Air Force element. The procedures employed by the MI Battalion (ARS) to complete

Figure 1. Aerial surveillance intelligence cycle.

the collection of intelligence information are covered in chapter 7.

- (3) *Intelligence production.* The field army G2 Air supervises the intelligence information returns to insure integration with other intelligence information available to the G2. The necessary imagery interpretation reports are submitted by MI Battalion (ARS) as established by SOP or as directed by the G2 Air.
- (4) *Dissemination.* The field army G2 Air supervises the dissemination of intelligence information to the requesting unit, thereby completing the aerial surveillance intelligence cycle.

c. Corps Aerial Surveillance Intelligence Cycle. The aerial surveillance intelligence cycle (fig. 1) at corps is comparable to that of the field army. The corps normally has Air Force reconnaissance missions allocated to accomplish immediate aerial surveillance and reconnaissance missions only. The G2 Air at corps develops his aerial collection plan based on the corps commander's requirements and the integration of approved requests received from subordinate elements. The G2 Air determines which missions can be accomplished by organic Army aircraft, and assigns them to the corps Aerial Surveillance Company for accomplishment. Preplanned missions requiring Air Force support are forwarded to the G2 Air at field army for approval and incorporation into the field army aerial surveillance plan. Immediate missions requiring Air Force support are coordinated with the DASC at corps and accomplished as part of the immedi-

ate missions allocated to the corps. The production and dissemination of the resultant intelligence are similar to those procedures of the field army aerial surveillance intelligence cycle. The actions taken by the corps Aerial Surveillance Company to coordinate, receive, and interpret the imagery they collect are discussed in chapter 8.

d. Division Aerial Surveillance Intelligence Cycle. The cycle at division is similar to corps. To the maximum extent possible, the division G2 Air attempts to accomplish requests from subordinate elements using his organic capabilities; i.e., visual aerial surveillance for all divisions, the aerial surveillance platoon in the airmobile division. Where this is not possible, he incorporates approved requests into the division surveillance plan which is forwarded to corps for approval and accomplishment within the resources of higher headquarters. Division missions flown by organic corps aircraft are coordinated beforehand so that ground sensor terminals and division imagery interpretation support may be alerted to receive the results of the mission as it is flown and the results processed and interpreted. The production and dissemination of the resultant intelligence are similar to the process employed at corps and field army.

e. Aerial Surveillance Intelligence Cycle for Other Units. The pattern for obtaining information through the use of aerial vehicles is similar at all echelons having organic aerial surveillance vehicles. Units without aerial surveillance means submit requests to the next higher echelon for appropriate action.

CHAPTER 4

AERIAL SURVEILLANCE AND RECONNAISSANCE MISSIONS

Section I. TYPE MISSIONS

15. General

There are two broad categories of missions—airial surveillance missions and aerial reconnaissance missions. Each type of mission is performed for a similar purpose; however, their planning and implementation differ.

16. Aerial Surveillance Missions

A surveillance mission is characterized by the greater expanse of terrain that it covers and the repetitiousness with which it is flown. Aerial surveillance is continuous over the entire battlefield or area of interest. Generally it is conducted without regard to specific targets though major areas of interest may be emphasized. A surveillance mission normally is performed with a large area coverage sensor such as radar, or by visual observation from higher altitudes so that a large ground area can be observed at all times. The majority of aerial surveillance missions will be flown on a repetitive basis, with individual flights overlapping to insure complete coverage of the area. Both radar and visual surveillance flights can be flown along or behind the FEBA parallel to the line of contact. Surveillance overflights of enemy occupied areas are also employed using visual observation or radar coverage to both sides of the aircraft's line of flight. The major advantages of surveillance missions are their ability to—

a. Cover large expanses of terrain rapidly and continuously, with the minimum expenditure of aircraft and sensor capabilities.

b. Maintain continuous surveillance over the entire area while flying over friendly positions which increases the capability for aircraft to complete successfully the mission and return safely.

c. Observe movement or changes as they take place on the enemy side of the FEBA which will provide the commander with an early warning of possible enemy intentions and identify specific target areas for further observation by either aerial or ground reconnaissance measures.

17. Reconnaissance Missions

A reconnaissance mission is characterized by its direction toward one or more specific target areas without the requirement for continuous coverage. A reconnaissance mission may be developed because of specific information indicating that an area possesses intelligence value, or because current or planned operations indicate a specific area is of significant importance and warrants more detailed coverage. Reconnaissance missions may be one time only, or periodic, but they are generally more restrictive than surveillance missions in their size and scope of coverage. A reconnaissance mission is ordinarily flown by penetrating the enemy airspace; however, some target areas can be adequately covered while flying behind the FEBA. Because of the type target involved, the need for greater detail, and the characteristics of the different sensors employed to procure the intelligence information desired, reconnaissance missions generally are flown at low altitudes. The major advantage of reconnaissance missions is the added detail for comprehensive intelligence study gained by concentrating the aircraft-sensor capabilities over specific targets.

18. Mission Requests

Aerial surveillance and reconnaissance missions are classified as either preplanned or im-

mediate. The majority of mission requests are preplanned, and are for surveillance type missions. Immediate mission requests are usually for reconnaissance type missions.

19. Preplanned Missions

Anticipated requirements for aerial surveillance or reconnaissance missions to collect needed intelligence information are met by preplanning their scheduling and accomplishment. A preplanned mission is the most efficient and economical type of mission since it allows sufficient time for thorough coordination, planning, briefing, and consolidation of requirements. It also permits proper selection and allocation of aircraft and sensors and eliminates the wasting of capabilities by assuring that all available airborne platforms are programed for specific mission accomplishment. The proper interpretation, integration, and dissemination of the information gathered can also be programed into the total work effort.

20. Immediate Missions

Immediate missions are characterized by the urgency of time involved between request for and receipt of information. Unforeseen requirements for intelligence of immediate tactical value triggers the need for immediate missions. A portion of the overall aerial surveillance and reconnaissance effort normally is held on a standby basis to meet such contingencies. The percentage of the total effort reserved to accomplish immediate missions varies with the tactical situation. For the Air Force, the percentage is determined by coordination between the G2 Air and the TACC. For Army resources, the determination is made as part of the daily air planning conference conducted by the G2 Air. In addition to the use of specifically designated aircraft to accomplish immediate missions, aircraft that are airborne on missions of lesser impact may be diverted and given the immediate mission for accomplishment.

Section II. COLLECTION MEANS

21. General

Aerial missions are further classified according to the type of mission and/or sensor used; visual, permanent record imagery, electronic intelligence, and weather. Any or all of these types may be necessary to support an area of operations. Aerial surveillance missions generally are inter-related and of complementary significance in terms of the information produced. Much of the intelligence information gained through aerial surveillance accrues to the benefit of all services, regardless of the purpose or unit for which it was obtained.

22. Visual Aerial Surveillance and Reconnaissance

a. General. Visual aerial surveillance and reconnaissance provides a rapid means of collecting intelligence information of the enemy area of activity through observation by aircraft crews. The value of visual aerial surveillance lies in the speed with which information of fleeting targets can be relayed to friendly units capable of attacking those targets. Vis-

ual observations may be augmented by the use of photographic equipment and in-flight voice recordings to provide a permanent record of the sightings and to increase accuracy and detail. For detailed discussion on aerial observation techniques and procedures, see FM 1-80. There are four general types of visual aerial surveillance—

- (1) *Area search.* An area search normally is conducted for the purpose of covering a general area, monitoring any movement within an area, detecting military activities, or monitoring movement of civilian populations. The limits of the area to be searched are designated in the mission request; however, the aircraft crew must plan the actual flight pattern to be flown to insure complete target coverage and successful mission accomplishment. Search areas will vary in size dependent upon the tactical requirements.
- (2) *Specific search.* A specific search normally is conducted to detect military,

paramilitary, or significant civilian activity within suspected, probable, or known locations. A specific search usually is employed for point targets and for specific information. A special form of specific search is contact reconnaissance in which an aerial observation mission is undertaken to locate friendly units that are isolated or cut off from the main force; e.g., a long range patrol out of contact with higher headquarters.

(3) *Route reconnaissance.* Observation of roads, railroads, waterways, and coastal and international borders may be conducted to determine enemy activity or lack of it. It may also be conducted to determine the adequacy of roadways, bridges, and other installations for our own use. Usually it is performed on a point-to-point or town-to-town basis over a selected route which may pass through several search areas.

(4) *Artillery adjustment.* The aircraft normally employed for surveillance and reconnaissance missions can be used to conduct indirect fire adjustment missions when the requirements exist and the priority of employment will permit. Normally fire adjustment missions for artillery or naval gunfire will result from in-flight reports rendered by the aircrew or from an immediate request of a supported unit.

b. Limitations of Visual Aerial Surveillance. Much information is collected by a trained and experienced observer; however, he is limited by the speed and vibration of the aircraft, visibility conditions, enemy concealment measures, and the distance from which he must observe as a result of the influence that terrain and enemy air defense may have on the aircraft. Many limitations of visual aerial surveillance may be overcome by using sensory and light intensification devices and binoculars to replace, verify, or supplement visual sightings.

23. Types of Permanent Record Imagery

a. General. Permanent record imagery is

essential before, during, and after an operation. All commanders require information concerning the strength, location, and disposition of the enemy. Aerial imagery normally can meet this requirement by providing recorded images which are studied, analyzed, and interpreted. Such analysis provides more detail and accuracy than that derived from visual observation. The use of permanent record imagery requires sensory and recording equipment of various degrees of complexity. A limitation of imagery is that the time lag between acquisition and interpretation may reduce or negate the value of information collected on transient and fleeting targets. Permanent record imagery may be obtained through the use of —

- (1) Conventional photographic cameras.
- (2) Infrared sensor devices.
- (3) Radar.

b. Classification of Conventional Photography. Conventional photography is classified according to the camera position and the area of coverage.

(1) Classification according to camera position is as follows:

(a) *Vertical.* Coverage of a target with photography taken from directly overhead. It provides photography of relatively constant scale, and allows the interpreter to get the best stereovision and most accurate measurements.

(b) *Oblique.* Coverage of a target area with the photography taken at an angle from the vertical. Oblique photography presents a view of the target similar to the view the pilot has of the target while flying toward or parallel to it. Oblique photography closely resembles the normal eye view and allows an interpreter to "see" into an area in a normal fashion instead of seeing the target as it appears from directly overhead. High oblique photography includes a portion of the skyline behind the target area; low oblique photography does not. Oblique photography taken with an 80 percent overlap between frames will allow stereoviewing.

- (c) *Panoramic photography.* Panoramic photography is taken with a special camera that scans across a wide area of the terrain, usually from horizon to horizon. It provides rapid photographic coverage of large areas of the terrain on both sides of an aircraft's line of flight in only one pass over the target area.
- (2) Classification according to area of coverage is as follows:
- (a) *Pinpoint.* Photography of a single point, feature, individual target, or small area of terrain which can be covered with a very small number of photographs. A minimum of 60 percent overlap between individual photoframes is necessary to assure stereoviewing.
- (b) *Strip photography.* A continuous series of overlapping photos taken in a single flight line which covers a lengthy target or large area of terrain.
- (c) *Continuous strip photography.* Continuous strip photography which provides a single strip of photography containing an unbroken image throughout the length of the flight line. This type of photography requires a special camera and eliminates the need for individual photoframes with overlap throughout the length of the strip.
- (d) *Area photography.* Two or more strips of photography which overlap to the side. Area cover requires a minimum of 30 percent sidelap between strips in addition to the 60 percent overlap between frames in order to provide stereoviewing throughout the area of coverage. The main use of area cover is in planning or for comparison of coverage by inspection with other imagery available. Area cover with the proper overlap and sidelap can be used to make photomosaics. Normally area cover is composed of vertical photography.
- (e) *Mapping photography.* Mapping or charting photography is taken for the purpose of preparing or revising maps and charts. Usually it is taken at much smaller scales than intelligence photography and should be used for intelligence purposes only when no other intelligence photography is available. This photography is taken with special stabilized cameras and other equipment, and the flight pattern and elevation of the aircraft are carefully controlled.
- c. *Infrared (IR) Imagery.*
- (1) An IR system is a passive sensor which detects emitted and reflected thermal radiation coming from the terrain and objects on the terrain. Current IR systems filter out reflected radiation and only record that radiation emitted by the object. The total emitted radiation is a function of an object's temperature and its emissivity. Emitted radiation will differ between objects and the resultant differences will be sensed and recorded by the IR system. The IR sensor can detect minute differences and, therefore, differentiate between objects close to each other. To achieve the maximum capability, the IR system must operate at low altitudes and its scan coverage is limited to the area directly below the flight-path of the aircraft; therefore, it is used normally only for point, linear, or small area targets.
- (2) IR aircraft are equipped for both a realtime pictorial display of the IR returns as the aircraft is passing over the terrain, and the recording of the sensor information on strips of film for later development and interpretation. Army IR aircraft can also transmit their imagery to a ground sensor terminal (GST), thereby providing a realtime presentation of the target area to personnel on the ground. The GST also records these presentations on film; however, both the film from the aircraft and

the film from the GST must be processed by an imagery processing facility before they become permanent record imagery and can be interpreted by trained image interpreters.

d. Side Looking Airborne Radar (SLAR).

- (1) SLAR is an active electronic device which emits energy and senses that portion of the emitted energy which is returned by reflection off of the terrain and objects thereon. The radar's energy may be directed at terrain to the left, right, or both sides simultaneously along the flight-path of the aircraft. The energy that is reflected from objects on the ground, both fixed and moving, are recorded on strips of film. It should be noted that since the radar pulse is line-of-sight, any high ground or tall objects in the path of the radar pulse will block out radar returns from any smaller objects which they mask. This causes SLAR returns to leave blank spots, called radar shadow, wherever these hidden areas occur.
- (2) The SLAR produces two films simultaneously; one depicts fixed target information (FTI), such as terrain features and buildings, and the other depicts moving target information (MTI); however, in order for the SLAR to acquire MTI, movement of the object must be greater than 3 MPH. These two strips of film when developed are called SLAR imagery. Army SLAR aircraft are equipped to continuously process exposed film and provide the airborne sensor operator a pictorial display of the returns while the aircraft is still in flight. Time delay from the film exposure until it is developed and ready for viewing is approximately 2 minutes. Army SLAR aircraft possess the same capability as Army IR aircraft for transmission to ground sensor terminals. At the GST these sensings are recorded on film, developed, and ready for viewing by imagery interpreters in approximately 2 minutes.

24. Electronic Intelligence Reconnaissance

Electronic intelligence reconnaissance is used to collect information on the location and type of enemy noncommunication electromagnetic radiations and their radiating emitters. It is sometimes known as "ferreting." Enemy noncommunication electromagnetic radiations can seriously impede the operations of friendly air defense radars. Information on the pertinent characteristics of the radiation and their emitters is of importance to our air defense personnel. This information is also used for other purposes, some of which are to determine—

- a. The enemy electronic order of battle.
- b. The most effective countermeasures to be taken.
- c. The effectiveness of enemy radar surveillance systems.

25. Weather Reconnaissance

Weather reconnaissance is conducted to obtain weather data over areas where weather reports are not available. The two basic methods of accomplishing weather reconnaissance is by taking instrumented atmospheric measurements and by making visual observations. Normally weather reconnaissance is performed by Air Force weather reconnaissance elements; however, Army aircraft can perform limited visual weather observation for the command. Weather reconnaissance is accomplished to obtain—

- a. Weather data for use in preparing weather analyses and forecasts. Missions which obtain such data fall into two general classes. Scheduled missions make weather observations, to include atmospheric surroundings, at predetermined locations and at scheduled times. Unscheduled missions investigate doubtful weather conditions which will affect the battle area.

- b. Special reports of weather conditions along the routes to, and in the vicinity of, targets for proposed air operations. These reports are required to permit immediate operational decisions such as diversion of aircraft, changes of flight tracks, or cancellations of missions.

- c. Special reports of weather conditions

that might have a significant influence on enemy capabilities.

26. Categories of Permanent Record Imagery

The three categories of permanent record imagery commonly used by the image interpreter are initial record, general intelligence record, and detailed intelligence record. The availability of improved imagery interpretation equipment in the Tactical Imagery Interpretation Facility (TIIF), has allowed the usable scales of photography to be increased in each category as indicated in *a* through *c* below.

a. Initial Record. Initial record is complete, permanent imagery coverage—usually flown seasonally—of a projected or actual area of operations generally extending from the line of contact with enemy ground forces to deep within the enemy territory. Photographic coverage normally will be of small scale (1:20000 to 1:60000), and suitable for stereoscopic study. Initial record provides basic information about enemy installations and defenses, cultural features, trafficability, soil, and vegetation. Its principal purpose is to provide a basis for evaluating changes in enemy-occupied territory. Areas subject to seasonal changes are recorded under conditions characteristic of each season to eliminate the observed differences caused by seasonal variations. Vertical initial record may serve as a map substitute or supplement. The field army normally supervises the automatic initial distribution to subordinate units according to areas of interest; supplementary issues are made as necessary. Typical allowances are shown in FM 101-10.

b. General Intelligence Record. This is vertical medium scale (1:10000 to 1:20000) imagery coverage within the field army area of interest. It provides current intelligence information and is compared with initial record imagery to determine current location and disposition of enemy installations, troop concentrations, troop movements, equipment, and

supplies. Normally this type of imagery is requested by division and higher headquarters.

c. Detailed Intelligence Record. In order to supplement the general intelligence record by providing large scale imagery of areas of specific interest, detailed intelligence record is obtained. It provides the imagery for detailed analysis of specific enemy activity, selected terrain features, installations, or equipment. It is frequently necessary to use more than one sensing or recording system over the target. Shown in (1) through (4) below, are types of detailed analysis.

- (1) *Vertical analysis.* The study of large scale (1:10000 and larger) photography reveals the plans and heights of installations not shown in general intelligence record.
- (2) *Oblique analysis.* The study of air photographs taken at an angle from the vertical will reveal installations from the elevation viewpoint. This type of imagery is particularly important in the analysis of features not suitable for vertical analysis, such as concealed or well-camouflaged installations.
- (3) *Concealment analysis.* Installations and equipment hidden from observation may be detected and subjected to study by special recording techniques; e.g., a camouflage net located through general intelligence record imagery may be identified as a covering for mechanical equipment when the area is subjected to infrared search.
- (4) *Deception analysis.* Enemy measures designed to deceive and confuse friendly intelligence collection agencies may be detected through analysis and comparison of photographic and electronic presentations such as radar, infrared, and electronic intelligence, collected at or near the same time.

CHAPTER 5

AERIAL SURVEILLANCE AND RECONNAISSANCE PLANNING OPERATIONS, AND COORDINATION

Section I. GENERAL PLANNING

27. General

Aerial surveillance and reconnaissance planning is conducted to provide assistance to the commander in the accomplishing of the unit mission. In preparing his plan, the G2 Air must consider all requests received from subordinate units as well as those requests generated by his own headquarters. He must integrate those requests from subordinate units which he approves with his own requirements to produce the total aerial surveillance and reconnaissance plan for the commander.

28. Planning Principles

Principles considered in planning are—

a. Essential Elements of Information (EEI). Generally, the EEI will serve to indicate the aerial surveillance to be planned for and requested. The G2 Air develops the plan for the command and establishes priorities based on the EEI and other guidance furnished by the G2. He insures that the plan will yield the information required to support the tactical planning.

b. Economy of Force. Economy of force is the planned use of equipment to obtain a maximum return from available resources. It is attained through the consolidation and integration of requests and tasks, the denial of requests which would duplicate information currently available, and the allocation of the available effort in relation to the requirements and priorities established.

c. Flexibility. Maximum flexibility is gained by the selection of alternate objectives and/or sensor means. This is especially true during

periods of marginal visibility; e.g., a photographic mission where unexpected cloud cover may occur over the primary area of interest. The aircraft may be diverted either to a secondary target or an alternate sensor may be used which can acquire some useful imagery when the preselected sensor would have been nonproductive.

d. Priorities. All aerial surveillance requests are identified by priority. The basis for determination of priorities is the urgency and importance of the requested information to support the operations of the requester. This is influenced by the unit mission, tactical situation, and the purpose for which the surveillance is intended. Normally, only a Roman numeral is used to indicate to the higher G2 Air the priority based on the importance of the requirement to the unit submitting the request; however, these priorities may change at higher echelons when considered in the overall tactical situation. Priorities, with their identifying Roman numeral, are—

- (1) *Priority I.* Surveillance of enemy units or activities, to include nuclear delivery means, that could *prevent*, or is preventing, the accomplishment of the friendly force mission.
- (2) *Priority II.* Surveillance of enemy units or activities capable of *immediate* serious interference with the friendly force mission; and the surveillance required in the conduct of current tactical operations.
- (3) *Priority III.* Surveillance of enemy units or activities capable of *ultimate* serious interference with the mission;

Tactical Action	Situation and General Considerations	Area Reconnaissance Emphasis	Specific Information Sought
Withdrawal	<ol style="list-style-type: none"> 1. G2 Air can expect: <ol style="list-style-type: none"> a. Enemy air superiority. b. Limited TAF support. c. Fast moving fluid situation. d. Possible non-availability of initial record and general intelligence record imagery. 2. The G2 Air should plan to: <ol style="list-style-type: none"> a. Use organic aircraft for primary support. b. Use immediate missions to meet the requirements developed by the fluid situation. c. Use visual air reconnaissance to meet the requirements for timely reporting of information. 3. If friendly air superiority is obtained, G2 Air should: <ol style="list-style-type: none"> a. Plan full use of available TAF visual reconnaissance. b. Coordinate with G3 Air for use of armed aerial reconnaissance. 	<ol style="list-style-type: none"> 1. Areas in which enemy is applying or has capability of applying most pressure. 2. Areas most likely to be occupied by enemy as indicated by knowledge of his tactics, deployment and reserves. 	<ol style="list-style-type: none"> 1. Enemy avenues of approach. 2. Troop movement (type and size). 3. Displacement of weapons. 4. Movement of reserve units. 5. Location and condition of obstacles including choke points. 6. Location of command posts, supply and evacuation establishments.
Defense	<ol style="list-style-type: none"> 1. Since defense is normally a prelude to the offense, G2 Air must: <ol style="list-style-type: none"> a. Detect enemy buildup for defense or attack. b. Assist in planning for friendly attack. 2. The G2 Air at corps and division should determine enemy buildup by: <ol style="list-style-type: none"> a. Employing organic aviation to keep enemy under surveillance. b. Employing non-organic aerial reconnaissance to extend depth of coverage. 3. The G2 Air should assist in planning for friendly attack by: <ol style="list-style-type: none"> a. Continuing surveillance along entire front, concentrating along planned axis of advance. b. Determining areas to be reconnoitered. 	<p>Even distribution of reconnaissance across entire front with emphasis on:</p> <ol style="list-style-type: none"> a. Areas of greater enemy activity. b. Areas in which friendly activity is contemplated. 	<ol style="list-style-type: none"> 1. Detection of enemy buildup. <ol style="list-style-type: none"> a. Location and estimated strength of enemy units along FEBA. b. Location, type and estimated strength of enemy reserve. c. Location enemy supporting weapons. d. Location enemy observation posts. e. Location enemy avenues of approach. f. Location command posts and supply points. g. Location enemy armor. h. Enemy troop movement. i. Location of obstacles. 2. Preparation for attack. <ol style="list-style-type: none"> a. Continuous study of comparative cover vs initial record imagery. b. Special imagery cover and studies: <ol style="list-style-type: none"> (1) Trafficability. (2) Enemy strong points. (3) Condition of railways and marshalling yards. (4) Condition of enemy airstrips to determine feasibility of friendly use. (5) Friendly avenues of approach. c. Continuous location of enemy reserves with emphasis on armor.
Attack	<p>The G2 Air can expect a fluid situation in which maximum support by air reconnaissance of the TAF is available. The G2 Air should:</p> <ol style="list-style-type: none"> a. Use direct observation to meet requirements for timely exploitation and reporting of information. b. Adjust depth and size of area to be reconnoitered based on rate of advance. c. Make maximum use of night visual, photographic and electronic surveillance. 	<ol style="list-style-type: none"> 1. Concentrated in front of main attack. 2. Areas occupied by enemy reserve forces (especially armor). 	<ol style="list-style-type: none"> 1. Movement enemy units (to and from FEBA). <ol style="list-style-type: none"> a. Actual movement (type, size, direction). b. Location of vacated areas. c. Location newly occupied areas. 2. Movement enemy reserve. 3. Displacement enemy supporting weapons (type, number and direction of movement). 4. Enemy resupply activities. 5. Location and condition of obstacles.

Figure 2. Planning factors for aerial surveillance and reconnaissance.

and the surveillance required to support planned future operations.

- (4) *Priority IV*. Surveillance of enemy units or activities capable of *limited* interference with the mission; and the surveillance required for administrative and logistical purposes.

e. Cover and Deception. The implementation of cover and deception measures must be considered when scheduled aerial surveillance missions over the combat area could compromise the operation by indicating unusual interest in that area. The G2 Air must expect to divert a part of the surveillance capability to implement cover and deception activities. Some cover and deception measures available are—

- (1) Reducing the number of missions over the area of interest.
- (2) Simulating interest elsewhere.
- (3) Controlling flight lines within the area of interest to obtain a random appearance.
- (4) Integrating reconnaissance missions with offensive missions.

29. Planning Factors

The major factors considered in planning in view of their effect upon the tactical situation and upon aerial surveillance missions are—

a. Friendly and Enemy Situation. The G2 Air considers the type and extent of planned operations in developing aerial surveillance plans (fig. 2).

b. Capabilities. The G2 Air considers the favorable and limiting characteristics of the sensors and platforms available, and the capabilities of the reproduction, interpretation, and dissemination agencies and their facilities.

c. Terrain. A study of the terrain is made to aid in determining probable enemy dispositions and courses of action. The G2 Air uses this information to plan missions and to assign priorities as necessary. Care is exercised to eliminate preconceived or fixed ideas regarding the enemy's use of terrain. Maps, charts, and data concerning tidal areas, canals, and rivers must be kept current. Seasonal tidal fluctuations have a direct impact on tactical operations.

d. Weather. Aerial surveillance plans are based upon predicted weather to exploit the proper sensor in the environment best suited to its operating characteristics. Planning is flexible to allow for variations between predicted and actual weather conditions.

30. Planning Phases

Aerial surveillance and reconnaissance planning is divided into two phases—long-range planning and day-to-day planning. The preponderance of effort in long-range planning is accomplished at field army level while the major effort at subordinate levels is in day-to-day planning.

31. Planning Sequence

a. The general sequence of planning is essentially the same for both the long-range and day-to-day phases of planning. The broad steps in the preparation of the plan by the G2 Air are accomplished in the following sequence:

- (1) Determination of the aerial surveillance and reconnaissance requirements.
- (2) Assignment of priorities to each requirement.
- (3) Integration of the requirements with the surveillance capabilities available.

b. General considerations of the G2 Air—

- (1) The unit mission as amplified by —
 - (a) Commander's concept.
 - (b) Unit's operational plans.
 - (c) EEI.
 - (d) Intelligence annexes.
- (2) Surveillance coverage of the entire zone of responsibility.
 - (a) Preparation of the aerial surveillance and reconnaissance plan.
 - (b) Integration of the aerial plan with ground reconnaissance and observation plans.
- (3) Coordination with higher, adjacent, and subordinate units.
- (4) Selection of areas for continuing priority emphasis.
- (5) Continuous planning.

c. Specific planning considerations of the G2 Air.

- (1) Study of terrain to determine the location and condition of obstacles

and traffic choke points, assembly areas, routes of approach, enemy positions, supply, and communications routes.

- (2) Study of areas rendered suspect by other intelligence sources.
- (3) Review of the latest weather forecasts.
- (4) Processing and consolidating all requests.
- (5) Coordination to insure the allocation of a portion of the supporting air effort is retained for immediate missions.
- (6) Planning maximum use of organic aviation.
- (7) Review of available imagery for adequacy to fulfill requirements before requesting new or additional imagery (master cover trace).
- (8) Coordination of ground and air intelligence efforts to obtain mutual

support, where possible.

- (9) Review of air request forms before transmitting to supporting air elements for accuracy and completeness and to eliminate duplication of effort.
- (10) Insuring that plans are commensurate with the capabilities of available aircraft, reproduction facilities, image interpreters, observers, and sensory equipment.
- (11) Insuring that all requirements levied on the G2 Air are provided for in planning.
- (12) Preparation of final aerial surveillance plans including assignment of tasks to subordinate units.
- (13) Insuring that communication security (COMSEC) considerations have been included in the aerial surveillance plans.
- (14) Continuing planning for daily operations.

Section II. SPECIFIC PLANNING

32. Long-Range Planning

a. Long-range aerial surveillance planning, prior to tactical engagement or the conduct of operations, begins with the receipt of a directive from higher headquarters, or the decision of the local commander. The planning establishes those requirements which must be satisfied to obtain the information essential to the commander. Planning is accomplished in the greatest amount of detail possible within the time available to the echelon at which the planning is done, and the capabilities of the supporting forces.

b. In those cases where the opposing forces have not yet engaged in combat, as in a landing by amphibious forces, the G2 Air bears an especially heavy portion of the responsibility for obtaining intelligence information. Before contact with the enemy, little or no intelligence data will come from subordinate units, since there will be no prisoners of war, patrols, observation posts, deserters, or line crossers to provide it. Thus, the G2 Air is called upon to acquire a greater proportion of intelligence than is true after contact has been made.

c. The first step which the G2 Air takes

is to develop a planning program for his branch. He does this in a manner similar to the procedures outlined in FM 30-5.

d. The G2 Air develops the reconnaissance and surveillance missions necessary to acquire the raw data. He coordinates with the supporting tactical air elements of other U.S. or allied services designated to operate with the Army. In addition, where organic aviation elements can accomplish aerial surveillance, he plans for, coordinates, and integrates the aerial surveillance and reconnaissance missions of these elements into his plan.

e. The processing of the incoming imagery and visual observation reports into usable form is the next step in the G2 Air effort. This necessitates having trained image interpreters properly briefed on the operation and directing them in the production of intelligence.

f. The final step in the G2 Air work is to prepare his output in formats most useful to the troops, agencies, and staffs who will become involved in executing the planned operation. Special maps and defense overprints, annotated imagery, terrain and defense analy-

ses, and up-to-date tactical maps are examples of the results of well-planned and thoroughly coordinated G2 Air operations in the planning phase.

33. Day-to-Day Planning and Operations

The same procedures discussed in paragraph 32 are used in day-to-day planning and operations. The commander's EEI and other intelligence requirements (OIR) developed by the G2 provide the G2 Air with the current priority tasks which must be accomplished. To provide for the orderly scheduling and accom-

plishment of these requirements, the G2 Air should utilize a collection plan (app B). The EEI and OIR are listed on the plan and the indicators are developed for each task. From the listed indicators, the broad requirements are developed as the basis for the aerial surveillance and reconnaissance plan, and the specific requirements for all collection agencies are developed. Because of the time lag in the aerial surveillance cycle, specific requests should be prepared as far in advance as possible.

Section III. REQUEST PROCEDURES

34. Preplanned Requests

a. The initiation, receipt, processing, and implementation of preplanned requests are basically the same at all levels. They are developed through prior planning and careful consideration and deliberation at all echelons before being submitted to the next higher headquarters. They represent the total known needs of the command as of the time of their submission.

b. At each level, when a request is received it is entered in an aerial surveillance log, a type format for which is shown in figure 3. The G2 Air duty team chief integrates all approved requests received into his own plan, then prepares a draft of the overall plan for the command and submits it to the G2 Air for approval. In formulating the plan, organic army aircraft are considered for all missions which fall within their capabilities. Consideration is also given to the capabilities of aircraft from supporting artillery and combat support elements when they are able to furnish a portion of the visual surveillance requirements of the combat zone. Missions which cannot be accomplished by organic means will be tentatively identified for accomplishment by the Air Force. Below field army level, the approved plan is submitted to the next higher headquarters for consideration and inclusion into its own plan.

c. At field army level the plans from lower echelons are integrated by the G2 Air into the field army's own plan to form the total field army plan. This is submitted to the G2 for

approval. After approval, the plan is coordinated for execution. When available, missions within organic aircraft capabilities are assigned to Army units for accomplishment. All other missions are coordinated by the G2 Air or his representative with the TACC at a daily planning conference. Requests are scheduled according to their priority against the total number of Air Force sorties allocated to support the field army, minus the number of sorties which the G2 Air indicates will be sub-allocated to subordinate corps to support their immediate operational needs. After agreement between the G2 Air and TACC has been reached, subordinate corps are notified of the final plan and the immediate missions are allocated.

d. Mission numbers, call signs, and other data for approved Air Force missions are received from the TACC and for approved army missions from the flying unit, and the information is posted on the mission status board. A type mission status board is at figure 4. Pertinent information on all missions is disseminated to the requester. The Military Intelligence Battalion (ARS) is also kept informed on all Air Force missions.

e. During daily operations, changes in the preplanned missions may be required due to change in unit mission, enemy situation, weather, or aircraft availability. The G2 Air or his representative coordinates with the TACC on necessary adjustments in Air Force preplanned missions, and with the organic Army flying units, if provided to the command,

MISSION NUMBER	ARMY/ AF	NR OF ACFT	COMMUNICATIONS		OPERATIONAL TIME			TYPE MISSION	TARGET AREA, ROUTE, POINT, OTHER	REMARKS

Figure 4. Type mission status board.

on adjustments in Army preplanned missions, on a continuous basis.

35. Immediate Requests

a. Immediate requests that originate at field army are submitted directly to the G2 Air duty team in the FATOC. The request is processed in a manner similar to a preplanned request. The duty team chief will—

- (1) Analyze the requirement against the current situation.
- (2) Determine if requested information is currently available, duplicates another mission, can be accomplished by organic Army means at a lower echelon, or must be accomplished by Air Force means.
- (3) Review preplanned missions to see if a mission already airborne could assume the immediate requirement.
- (4) Determine if information required can be obtained in time to be of value.
- (5) Establish the mission priority.
- (6) If disapproving the request immediately, notify the requestor of the reason for disapproval.
- (7) If approved, pass the request to a subordinate G2 Air for accomplishment by Army means, or to the TACC for accomplishment by Air Force means.
- (8) Provide the Military Intelligence Battalion (ARS) with information and special instructions on approved Air Force missions.
- (9) Post the mission on the mission status board.
- (10) Notify the requestor of the scheduled aircraft time over target, the radio call sign, and the frequency assigned to the aircraft.

b. Immediate requests originating at corps are submitted directly to the corps G2 Air or his representative in the corps TOC. The immediate requests are processed in the same manner as those that originate in field army with the following exceptions:

- (1) Approved requests not within Army aviation capabilities are submitted directly to the DASC at corps level rather than to the TACC.
- (2) Information required to properly

brief the flying crew and assist in the interpretation and dissemination of the resultant intelligence information collected is furnished directly to the organic Army aviation unit, or to the MIBARS detachment and to the ARLO collocated with the TAF reconnaissance squadron which has been scheduled to perform the mission.

- (3) The field army G2 Air will be notified of approved requests and of that information that was furnished directly to the MIBARS detachment.

c. Immediate requests from echelons below corps (fig. 11).

- (1) Maneuver battalions, brigades, division, or separate units that have a direct support TACP with their headquarters submit immediate requests directly to their direct support TACP. Units that do not have a TACP submit immediate requests through command channels to the first higher headquarters with a TACP. At the TACP, the request is transmitted over the Air Force air request net directly to the DASC at corps. All intermediate TACP between the requester and the DASC monitor the request and notify the S2/G2 Air. If the intermediate S2/G2 Air does not object to the request, he has his TACP signify approval by remaining silent on the net. If, however, the S2/G2 Air disapproves the request, he passes his disapproval to both the corps G2 Air and the originator of the request over the TACP communication facilities. In arriving at a decision to approve or disapprove the request, each S2/G2 Air, from maneuver battalion to corps, evaluates the request to see that it is valid; if it can or cannot be met from intelligence information already at hand; if it can or cannot be accomplished by Army means; or if it is or is not part of a surveillance and reconnaissance mission already in progress.

- (2) At the DASC, the Air Force recon-

naissance officer will coordinate the request with the corps G2 Air. If the G2 Air disapproves the request, the DASC will notify the requester of the disapproval through the TACP. If the G2 Air approves the request, the DASC will then direct one of the TAF reconnaissance squadrons to accomplish the mission. Once approved by the G2 Air, the request and the mission flight information are furnished to the appropriate MIBARS detachment and ARLO, and the field army G2 Air as discussed in *b* above.

36. Requests for Other Type Missions

a. Artillery Adjustment. Requests for adjustment of artillery fire that cannot be accomplished by using Army aircraft are processed like other aerial surveillance requests. Requests are coordinated with the G3 Air at all levels prior to submission to higher head-

quarters in order to use, if feasible, Air Force close support aircraft already operating in the area or to control the adjustment of fire using an artillery forward observer in coordination with an Air Force forward air controller.

b. Electronic Reconnaissance. Requests for electronic reconnaissance are processed and forwarded in the same manner as other aerial surveillance requests; however, requests are closely coordinated with the Army Security Agency element at each level of command in order to accomplish the mission at the lowest possible level. When a mission is beyond organic capabilities, it is coordinated by the G2 Air at field army with the TACC for accomplishment with Air Force electronic reconnaissance resources.

c. Weather Reconnaissance. Requests for weather reconnaissance missions are processed in the same manner as other aerial surveillance requests.

Section IV. AIRCRAFT AND SENSOR CAPABILITIES

37. Platforms

a. Army aircraft are designed to perform visual aerial surveillance, aerial photography, infrared reconnaissance, radar surveillance, and electronic reconnaissance. The advantage of organic aircraft is in their quicker responsiveness to the commander's needs, their slower flying speeds, their ability to fly at very low altitudes which enhances visual observation, and their ability to operate from short, semi-improved runways or areas in close proximity to the supported forces. The disadvantages of organic aircraft are vulnerability to ground fire, short operational range, and their slow speed.

b. Air Force aircraft are designed to perform the same type of missions as Army aircraft with the addition of special radar mapping and weather reconnaissance operations. The advantages of Air Force aircraft are in their ability to photograph large areas, their greater variety of different camera systems that can be carried by a single aircraft, their high speed, their long operational ranges which allow deep penetration and rapid return of information, and their lower criticality to

loss by ground fire since they can operate at extremely high altitudes. Their disadvantages are that they operate at too high speed for detailed visual observation, and that they need to operate from improved landing fields.

38. Sensors

All sensors operate according to specific natural laws regarding a particular portion of the electromagnetic spectrum. Each portion of the spectrum reacts differently to natural phenomena. Visible light photography has the highest resolution, but is hampered during periods of reduced visibility such as rain, heavy clouds, and darkness. Infrared imagery is next in resolution; however, emitted IR energy is rapidly reduced by the heat absorbing characteristics of rain, snow, fog, clouds, and hail. Radar can operate at reduced capability through clouds and precipitation and other conditions of poor visibility. The capabilities of sensors become an important consideration in their selection (fig. 5). Each sensor is complementary to the others; i.e., optical imagery may find the object, radar may indicate its movement, and infrared may detect its heat emissions.

Figure 5. Sensor selection guide.

a. Photographic Imagery. Two major factors must be considered in planning photographic imagery missions; the desired scale of the imagery and the maximum utilization of the photographic mission itself.

- (1) Suggested minimum scales for detailed imagery interpretation have been extracted from TM 30-245 and are contained in appendix E. Factors influencing the choice of scale may include the type of information desired, cloud cover, light conditions, the type of platform, camera, lens, film used, and the air defense capabilities of the enemy.
- (2) Many requests for photographic imagery will be of small areas or pinpoint targets. In order to use the effort most economically, photographic requests are consolidated whenever possible. A mission is planned so that processing, reproduction, interpretation, and dissemination can be accomplished within the time required. Careful selection of the route to and from the primary target may allow inclusion of other surveillance requirements to be accomplished during a single mission.

b. Airborne Radar. Flight planning for the use of radar sensors considers the characteristics of radar waves. Radar waves of current sets do not penetrate heavy foliage or intervening terrain; therefore, the flight lines are planned to provide full coverage. Also, radar will not record targets moving exactly perpendicular to the aircraft line-of-flight; therefore, flight lines should be flown to avoid having major traffic arteries such as highways, waterways, and railroads within an area under surveillance run perpendicular to the line-of-flight. Airborne radar, principally SLAR, pro-

duces general intelligence record imagery with the primary emphasis on indications of moving vehicles. A primary advantage of SLAR is that imagery can be obtained without having to penetrate into enemy territory. The airborne radar system has a day/night, near all weather capability which can be employed during periods of low visibility when visual, photographic, or infrared surveillance measures are curtailed. Only conditions of extreme weather turbulence will adversely affect the radar results. Since radar is an active sensor, its energy output can be detected by the enemy and electronic countermeasures (ECM) can be employed to jam the signal or degrade the radar returns. Such countermeasures are only effective when the radar is operating within the immediate area in which the ECM is located. Radar imagery acquired prior to, and immediately after, passing an ECM device will remain unaffected.

c. Infrared. Airborne infrared detectors produce detailed or general intelligence record imagery by sensing radiated temperature variations between the terrain and objects on the terrain. By varying the type of detector used in the set, either an infrared image of the area being covered or a presentation of points of significant temperature variations may be obtained. This type of sensor is passive in that it does not depend upon detecting the reflection of transmitted energy as does radar. It is impossible to jam, but it may be deceived by the enemy's deliberate use of heat-producing devices. Infrared imagery, like radar, may be used for comparison or it may be used to locate areas of activity determined by the number and type of heat-producing elements detected. Rain, snow, hail, smoke, dust, and fog will reduce the sensor's ability to detect heat emissions. The IR aircraft must overfly the target area to obtain its imagery.

Section V. OPERATIONAL AIDS

39. General

The techniques used in planning and controlling aerial surveillance and reconnaissance require the development of operational aids. These vary in scope and complexity depending upon the requirements of the preparing eche-

lons. A complete listing of operational aids except for the G2 Air collection plan and aerial surveillance log which have been covered in paragraphs 33 and 34, is shown in figure 6 and discussed below.

CLASSIFICATION	TITLE	USE	PREPARING ECHELON

Figure 6. Aerial surveillance/reconnaissance operational aids.

40. Section SOP

The section SOP establishes necessary administrative procedures to insure the proper functioning of the G2 Air section. It includes the organization, responsibilities, and duties of personnel.

41. Aerial Surveillance Annex to the Unit Intelligence SOP

The aerial surveillance annex to the unit intelligence SOP establishes the administrative procedures for the command. It is initially prepared at field army, Corps, division, and lower units prepare their SOP in consonance with the guidance furnished by the next higher echelon. There is no prescribed format for this annex.

42. G2 Air Situation Map

The G2 Air situation map covers the command area of interest. It is similar in scope to the G2 situation map and is kept current by plotting key observations. It is a major planning aid used in developing specific requirements of subordinate commands. Requests, plotted on an overlay, are used to develop the specific requirements by consolidating where feasible and by eliminating duplicated requirements. The G2 Air situation map is used as a guide to determine the advisability and feasibility of approving immediate missions.

43. Aerial Surveillance and Reconnaissance Appendix to Intelligence Annex of Unit Operation Order

The surveillance and reconnaissance appendix to the intelligence annex of the operation order is used to disseminate orders to subordinate commands. Orders are either general or specific, dependent upon time and availability of information for planning, and are prepared in either written or overlay form (app C).

44. Daily Aerial Surveillance Plan

The daily aerial surveillance plan is a listing of approved preplanned missions. It serves as a statement of requirements for information and the means selected to satisfy them. The plan is disseminated to subordinate units to provide them with information on the time, type, frequency, and purpose of missions.

45. Aerial Surveillance Route, Area, and Point Overlays

a. General. Aerial surveillance route, area, and point overlays are prepared and used to rapidly designate preselected routes, areas, and points in aerial surveillance planning and operations. This system is applicable at all echelons.

b. Concept. The aerial surveillance and reconnaissance appendix to the intelligence annex of an operation order is supported by appropriate route, area, and point overlays which are identified as TABS A, B, and C respectively. Route (TAB A) and area (TAB B) overlays are always prepared in planning for aerial surveillance. A point overlay (TAB C) is prepared when necessary for locating points of primary interest.

c. Responsibility. The G2 is responsible for the preparation of route, area, and point overlays. They are coordinated with the TACC and incorporated into the aerial surveillance appendix. The actual coordination, preparation, and dissemination of the overlays is a function of the G2 Air.

d. Route Overlays. In the preparation of route overlays, selected primary lateral and axial (pertaining to the axis of advance) routes which have been determined to be of greatest tactical significance to the commander are drawn. Selected routes are identified by the letter R prefix (R-1 to R-50) for the numerical designation of axial routes, and a block of numbers with a Z prefix (Z-51 to Z-100) designates lateral routes (figs. 7 and 8). A selected route may not traverse the entire length or width of the area and, therefore, is terminated unless it can be tied to another route within 16 km. (Fig. 7 shows route R-1 terminated because of this distance factor.) Termination of an R-route, for example, can be avoided by traveling a Z-route for less than 16 km (fig. 8, point Y). When preparing route overlays, road nets, rail nets, waterway systems, prominent trails, and other features are selected that are recognizable from the air. When route planning is not adaptable to the particular terrain (jungle, arctic, etc.), reliance must be placed solely on search areas.

e. Area Overlays. Area overlays are pre-

20
+
70

Figure 7. Route overlay (TAB A)—route continuation, axial and lateral route identification.

pared to indicate the overall area of interest to the command that will require detailed visual aerial search. Normally the area of interest is divided into small, specific areas that can be searched with a single aerial mission. The size of an area which can be searched by one aircraft on one mission depends upon the aircraft used, the type of terrain to be covered, the enemy defenses in the area, the intensity of the search, the information being sought, and the capability of an aerial observer to visually search the area. Planning figures for area search operations must be developed by flying units through actual conduct of visual area search missions within the area of operations. Terrain features easily recognized from the air are used in defining the limits of the search area. For economy of time and aircraft, search areas should be oblong in shape to allow a minimum number of passes to ob-

tain complete coverage (fig. 9). In planning area overlays, the G2 Air places emphasis for surveillance on secondary routes and those primary routes not used in preparation of route overlays. The letters of the alphabet, with the exception of I, O, R, and Z, are used as prefixes to the numerical designations applied to search areas. When the area of interest has been subdivided into search areas, those nearest the line of contact are given the prefix A followed by a number; the areas in the next row are given the prefix B followed by a number; etc. This system is continued until all the selected areas have been identified with letters and numbers.

f. Point Overlays. The point overlay is prepared by the G2 Air in response to requirements to collect intelligence information and develop specific targets. In preparing the point overlay, the G2 Air selects key points of im-

20
+
70

Figure 8. Route overlay (TAB A)—route initiation and termination.

mediate or future probable intelligence interest that are vulnerable to pinpoint photography or rapid visual observation. These key points are usually readily identifiable from the air and will facilitate in-flight target location and reporting. A pinpoint representing a coordinate, surrounded by a circle with a numerical identification, is plotted on the point overlay (fig. 10).

g. Base Plans. All three overlays (TABS A, B, and C) are prepared prior to operations and are referred to as the base plan. The route, area, and point numerical designations are referred to as base plan index numbers. The base plan normally is given a security classification commensurate with the classification of the plan which it supports. In anticipation of compromise of any portion of the base plan, alternate alphabetical and numerical designa-

tions for each overlay should be established in advance. When a change of designators is required due to compromise, the necessary changes are announced by utilizing one or more of the cryptographic systems established in the command signal operations instructions (SOI) in use by all elements of the command. Examples of crypto systems which may be used are SOI operations codes or prearranged message codes.

46. Master Cover Trace

A master cover trace is an overlay showing the imagery available at an echelon of command or imagery interpretation detachment. It is used to indicate the status of current imagery available for a given area or target, thus preventing unnecessary waste of mission aircraft on duplication of effort. The master

Figure 9. Area overlay (TAB B).

cover trace normally is maintained by the unit providing the imagery interpretation support to the command.

47. Air Reconnaissance Request

a. Section I of the air reconnaissance request form (app D) is applicable for use by both the U.S. Armed Forces and all member nations of NATO. The format of section I complies with NATO Standardization Agreements (STANAG), Number 2102, Offensive Air Support Operations Message Formats, and Number 3277 (Edition No. 4), Air Reconnaissance Request Form. The information requested by

section I is furnished by the requester for each specific aerial surveillance or aerial reconnaissance mission submitted. Normally, requests are transmitted by electrical means and the actual form is completed at the headquarters where the request is received. The format of the request provides a means of reporting and recording sufficient information to locate and identify the area of interest and the specific information desired from the mission. The request may be initiated at any echelon and is used for both immediate and preplanned missions. The G2 Air, or appropriate intelligence staff office below division level is charged with

Figure 10. Point overlay (TAB C).

the responsibility for initiating the request in the proper format, and integrating the requirement into the aerial surveillance cycle for appropriate action. The back of the request form provides instructions for completing the request.

b. As a suggested guide for administrative control and processing of requests, sections II, III, and IV of the air reconnaissance request form are provided. These sections allow the recording of all actions taken on a request to be shown on the request form itself. Instructions for completing sections II, III, and IV are contained on the back of the form.

48. Request Overlay

A request overlay is an optional graphic supplement to the aerial surveillance request. Normally prepared by image interpreters, it indicates the image taking technique required to satisfy a special requirement to be accomplished by a particular photographic, infrared or radar mission. Examples of a special requirement include numerous changes in flight-paths or specific attitudes, angle and/or direction of flight, lengths of flight lines, and approach direction to a target area. A request overlay is only required if the mission must satisfy unusual interpretative requirements which cannot be presented adequately in the context of the actual air reconnaissance request format. This overlay is prepared jointly by the interpreter and the flying unit when circumstances permit.

49. Mission Status Board

A mission status board reflects the status of immediate and preplanned missions. Information about each mission is filled in as it becomes available. It assists the G2 Air in following the conduct of each mission and is a base from which to initiate changes in plans caused by changing situations. Each echelon maintaining a mission status board uses the format that best suits its operational needs. An example of a mission status board is shown in figure 4.

50. Missions Folders

Mission folders assist the G2 Air by segregating requests according to status of action. The following folders are maintained:

- a. Approved requests.
- b. Disapproved requests.
- c. Completed missions.
- d. Aborted missions. (Missions not completed due to weather, enemy air defenses, equipment malfunction, or rerouting of mission aircraft to higher priority mission while en route.)

51. Pilot Trace

A pilot trace is an overlay showing the pilot's concept of the course flown and the points at which imagery was exposed. It is used to assist interpreters in correlating the resultant imagery to the terrain.

52. Imagery Interpretation (II) Reports

Imagery interpretation reports and mission reports are discussed in chapters 9 and 10.

Section VI. COORDINATION

53. General

The G2 Air coordinates the aerial surveillance effort with those agencies and elements having an effect on, or affected by, the collection of intelligence through aerial means. This coordination is necessary for the efficient accomplishment of the aerial surveillance intelligence cycle, from the development of requirements to the dissemination of the intelligence produced. Coordination with the general and special staff sections of the command and with the G2 Air sections at higher, lower, and ad-

jacent headquarters as well as with elements that accomplish operational functions is essential.

54. The Field Army

The field army G2 Air works closely with the staff sections within the headquarters such as engineer, artillery, aviation, chemical, signal, air defense, and transportation. Close coordination for both long-range and day-to-day planning is conducted with the TACC, the Military Intelligence Battalion (ARS), the

Military Intelligence Battalion, Field Army, and attached Army Security Agency personnel.

55. Corps and Division

Both the corps and the division G2 Air coordinate in a manner similar to the field army G2 Air; however, such coordination is reduced in scope. Examples of corps coordination are with the corps engineer for mapping photography requirements or photomap reproduction, with the corps artillery section on target and damage assessment information, and with the corps signal officer on communication matters. The Corps G2 Air also coordinates with the Aerial Surveillance Company for mission support, interpretation, and reproduction of imagery. At division, coordination is conducted with the G3 for planned operations, with the division aviation officer regarding the availability of visual aerial surveillance means, with the division signal officer regarding communications and signal photographic reproduction support, and with the FSCE regarding damage assessment mission operations.

56. Army Security Agency

a. Integration of signal intelligence (SIGINT) and imagery intelligence at the earliest practical moment in the intelligence production effort is a clearly defined requirement to assure the most effective target ac-

quisition, surveillance, and reconnaissance support to the tactical commander. SIGINT information can complete, confirm, or refute, and, in many instances, serve as the basis for initiating additional reconnaissance and surveillance missions.

b. In order to facilitate timely integration, obviate handling delays normally incurred when dealing with special intelligence, and particularly to assist the tactical commander in the effective employment of SIGINT resources at his disposal, the U.S. Army Security Agency will provide an ASA qualified staff officer at army, corps and division, and attach ASA support units to each division and independent brigade. These units will provide personnel for a technical warfare element (TWE) in the TOC.

c. In order to effect proper coordination, the operations center of the supporting ASA unit will be located as close to the CP or TOC as feasible, in accordance with the supported commander's desire. It is located to provide optimum command and control over ASA deployed elements and at the same time be responsive to the requirements of the supported command. Secure communications between the ASA operations center and the CP or TOC will play a critical role in these operations.

CHAPTER 6

COMMUNICATIONS

57. General

a. Communication means for aerial surveillance and reconnaissance activities consist of voice radio, radio teletype nets, and other teletypewriter circuits using command multi-channel communications systems. These means provide communication facilities for both the transmission of requests for aerial surveillance and reconnaissance missions and the rapid dissemination of the intelligence information produced from aerial missions. The nets and equipment utilized include both Army and Air Force sources. Army equipment is either provided for in unit TOE or by the organic signal unit at each command level; Army communication is coordinated through the command signal officer. Air Force elements within the air-ground operations system provide the Air Force communication nets. Whenever possible, sole user point-to-point circuits are established through the area communications system to provide a backup means of communication.

b. The recent introduction of the Aerial Surveillance Company and the tactical imagery interpretation facility (TIIF) with its organic SSB-Voice-RATT communication equipment has required the development of new nets and means of communications between G2/S2 Air elements and the aerial surveillance and reconnaissance community. For this reason, this discussion of available communications means will include current communication nets as well as the new communications means dictated by these new organizations and equipment. In actual practice, portions of both the current and new communications systems may exist concurrently during the transitional period. Figure 11 depicts the current aerial surveillance and reconnaissance communication nets which are discussed below.

58. Current Aerial Surveillance and Reconnaissance Communication Nets

a. *Army Air Request Net.* The Army air request net provides AM (voice, CW, or RATT) communication, with integral security equipment, between armored cavalry regiments, divisions, corps, and the field army. This net is used jointly by G2 Air and G3 Air personnel to submit preplanned close air support and aerial surveillance and reconnaissance requests from lower to higher headquarters. There are as many Army air request nets as there are corps in the field army. The stations of the net have their terminals in the TOC at each echelon. These stations are provided and operated by the supporting signal unit at each level. The net control station (NCS) is located at the FATOC.

b. *Division Air Request Net.* The division air request net provides AM (voice-CW) communications, between maneuver battalions, brigades, the cavalry squadron, and the division TOC. This net is used jointly by G2/S2 Air and G3/S3 Air personnel to submit preplanned close air support and aerial surveillance and reconnaissance requests from lower to higher headquarters. There are as many division air request nets as there are divisions in the field army. The division station at the TOC is provided by the division signal battalion. The other stations are part of the unit TOE. The NCS is in the division TOC.

c. *Air Force Air Request Net.* Air Force communications means are provided for the submission of immediate requests for close air support and aerial surveillance and reconnaissance requests from lower to higher headquarters. Stations in this net exist at the TACP with each battalion, brigade, division, and at the DASC of each corps. The NCS for

Figure 11. Current aerial surveillance and reconnaissance communication nets.

the net is at the DASC. A detailed discussion on the operations of this net is contained in paragraph 35c.

d. Spot Report Receiver System. For the

rapid dissemination of important visual observations made by Air Force crews in flight, UHF radios are located at the field army (in the TACC), at corps (in the DASC), at the

division TOC, and at each brigade, maneuver battalion, and cavalry squadron. These radios are used to monitor the Air Force in-flight report net for in-flight transmissions. To insure complete dissemination of information received, the unit SOP should specify rebroadcast of reports as required over the division warning broadcast net or the division operations intelligence net.

e. Air Force Command Net. Air Force communications means also exist between the TACC, DASC, Tactical Air Force headquarters, and the Air Force flying units. This net provides the communication means for the TACC to task Air Force reconnaissance units on preplanned missions and provides both the TACC and the DASC with direct communications to Air Force flying units scheduled to accomplish immediate missions.

f. Additional Communications Means. Command SOP and SOI should establish normal traffic procedures for submission of immediate and preplanned requests over the nets discussed above. To provide additional means for submission, requests also may be transmitted over other nets that are available. At division level and below, the primary additional means consists of the brigade operations/intelligence net (between battalions and brigades), and the division operations/intelligence net (between brigades and the division headquarters). Alternate additional means at these levels include the brigade command nets, the division general purpose net, and the division command net. Above division level, the corps and Army command nets provide semiautomatic teletypewriter circuits with other RATT nets for alternate communication means. In addition to the Army communication nets, Air Force air request nets used for submission of immediate air requests also may be used for preplanned requests by establishing local Army-Air Force agreements. When Air Force channels are used, preplanned requests must be transmitted through all intermediate Army headquarters for necessary staff action.

59. New Aerial Surveillance and Reconnaissance Communications Nets

a. Military Intelligence Battalion, Air Reconnaissance Support, Field Army (MIBARS)

Operations Net (fig. 12). The MIBARS operations net (SSB-CW-voice) functions between the MIBARS detachments located with the AF reconnaissance squadrons, the MIBARS battalion operations and intelligence section (NCS), and the imagery interpretation team from the MIBARS battalion that supports the G2 Air at the TASE of the FATOC. (This new net replaces the former air reconnaissance liaison officer (ARLO) net and portions of the old Army information net.) This new net can carry imagery interpretation and ARLO reports and allows the field army G2 Air to pass information on immediate and preplanned missions directly to the MIBARS headquarters and its detachments.

b. Corps G2 Air-Aerial Surveillance Company Operations Net (fig. 13). This net (SSB-RATT-voice) provides communication between the Corps G2 Air at the TASE of the CTOC and the corps Aerial Surveillance Company. One imagery interpretation team with TIIF from the corps military intelligence unit, collocated with the G2 Air at the TASE, provides the communications for the G2 Air section, while the communications for the Aerial Surveillance Company is provided by TOE. The parent headquarters for the Aerial Surveillance Company has not yet been resolved in Army organization. When designated, the parent headquarters, which may be the military intelligence unit at corps, will be added to this net. Other TIIF organic to the corps military intelligence unit and the Aerial Surveillance Company are also added to this net when they are provided the necessary communications equipment. This net can carry imagery interpretation and debriefing reports from the Aerial Surveillance Company and other corps TIIF to the G2 Air. It also allows the G2 Air to pass requirements and information on immediate and preplanned missions directly to the Aerial Surveillance Company.

c. Division II Team Communication Equipment. The division G2 Air is supported by one imagery interpretation team with TIIF, at the TASE of the DTOC. This team has communication equipment that will net with the radio sets in the MIBARS and corps G2 Air-Aerial Surveillance Company operations nets; however, it is not a regular station in either net.

*NOTE: SENIOR ARLO W/AF RCN WING NORMALLY COLLOCATED AT SAME AIRFIELD W/ONE MIBARS DET AND UTILIZES ORGANIC DET COMMUNICATIONS EQUIP.

Figure 12. MIBARS operations net.

Figure 13. Corps G2 Air-Aerial Surveillance Company operations net.

d. Alternate G2 Air Means of Communications.

- (1) Communications equipment in the MIBARS operations net, the corps G2 Air-Aerial Surveillance Company operations net, and the division imagery interpretation team TIIF are

identical; they allow the establishment of communications between G2 Air sections at each level when required and authorized.

- (2) For immediate air requests approved by corps G2 Air, executing instructions are passed directly from the

corps DASC to the AF reconnaissance squadron. To match this responsiveness and insure that the Army ARLO and MIBARS detachment collocated with the AF reconnaissance squadron is also alerted and furnished with full information on the mission, the G2 Air at corps passes mission requirements directly to the MIBARS detachment over the MIBARS operations net. At the same time, the corps G2 Air must insure that an information copy of the mission requirements is also furnished the G2 Air at field army. This can be accomplished by including the field army G2 Air as an information addressee when transmitting the original message over the MIBARS net.

- (3) When missions flown by either the Air Force or the corps Aerial Surveillance Company result in information of significant tactical value, the appropriate MIBARS detachment, Aerial Surveillance Company imagery interpretation section, or ARLO having the information transmits the report directly to the requester utilizing the common facilities at each echelon. However, information transmitted must also be reported to the respective G2 Air as expeditiously as possible.

60. Other Communication Systems

a. The field army area communication system may be used for routine aerial surveillance and reconnaissance operational traffic when other communication systems require supplementation.

b. Normal communications means used for aerial surveillance and reconnaissance operations, as discussed in paragraph 58, may become overloaded or reduced because of displacement of a headquarters. Provisions must be made at the alternate TOC to share other nets to insure that adequate means of submitting requests and receiving information continue to exist. When possible, Air Force nets may be utilized to carry priority operational traffic for the period of the move.

c. When missile commands support allied units, provisions must be made to augment their communications capabilities to provide a rapid means of requesting and disseminating aerial reconnaissance and surveillance information.

d. Army aircraft are equipped with radios capable of netting with the tactical radios of the ground elements. This provides a means of disseminating information of immediate tactical significance. Procedures, frequencies, and call signs to be used must be coordinated between the flying crew and the ground units prior to the flight or established in command SOP and SOI.

CHAPTER 7

MILITARY INTELLIGENCE BATTALION, AIR RECONNAISSANCE SUPPORT, FIELD ARMY

Section I. MISSION, ORGANIZATION, AND FUNCTIONS

61. Introduction

This chapter furnishes guidance pertaining to the operations and employment of the Military Intelligence Battalion, Air Reconnaissance Support, Field Army (MIBARS) and its organic elements.

62. Mission

The overall mission of the MIBARS is to produce and disseminate intelligence information obtained from Tactical Air Force reconnaissance elements operating in support of the field army and to provide liaison between the field army and the reconnaissance elements of the supporting Tactical Air Force.

63. Organization and Functions

a. General. A MIBARS is organized as depicted in figure 14. One battalion normally is assigned to each field army or independent corps. The functions of the MIBARS are to—

- (1) Process, interpret, annotate, reproduce, and deliver imagery obtained from the Tactical Air Force elements operating in support of the field army.
- (2) Coordinate imagery interpretation and reproduction functions from widely separated reconnaissance airfields and from the vicinity of the supported field army headquarters.
- (3) Disseminate all intelligence information obtained through imagery interpretation and visual aerial reconnaissance sightings by the supporting Tactical Air Force reconnaissance elements.
- (4) Provide air reconnaissance liaison officers (ARLO) to Tactical Air

Force reconnaissance elements operating in support of the field army.

- (5) Brief and debrief tactical air reconnaissance aircraft crews.

b. Headquarters and Headquarters Company. The mission of the headquarters and headquarters company, MIBARS, is to provide command, control, administration, and logistical support for the battalion; to perform detailed imagery interpretation for the field army; to provide the means for immediate dissemination of information and imagery to the using units on a 24-hour basis; and to provide liaison and coordination with the Tactical Air Force reconnaissance units supporting the field army. The functions of the headquarters and headquarters company, MIBARS, are to—

- (1) Provide command, control, and staff supervision for the battalion.
- (2) Coordinate operations with the Tactical Air Force reconnaissance elements in support of the field army.
- (3) Provide a senior ARLO to the major Tactical Air Force reconnaissance unit.
- (4) Provide administrative and logistical support for the battalion (with the exception of medical and religious facilities which must be furnished by other units).
- (5) Perform detailed interpretation of aerial imagery, as required.
- (6) Reproduce, identify, and package aerial imagery.
- (7) Deliver, as required, from each reconnaissance airfield to the field army headquarters, and to each corps and division of the field army.

**MILITARY INTELLIGENCE BATTALION, AIR RECONNAISSANCE SUPPORT,
FIELD ARMY**

Figure 14. Military intelligence battalion, air reconnaissance support, field army.

c. Military Intelligence Detachment, MIBARS. The mission of the military intelligence detachment, MIBARS, is to interpret

and reproduce aerial imagery obtained by the Tactical Air Force, and to provide liaison between field army and the Tactical Air Force

reconnaissance squadrons. The functions of the military intelligence detachment, MIBARS, are to—

- (1) Plot and perform immediate imagery interpretation and to prepare and disseminate priority imagery interpretation reports on a 24-hour basis.

- (2) Reproduce, identify, and package aerial imagery.
- (3) Provide liaison with reconnaissance elements of the Tactical Air Force.
- (4) Brief and debrief Air Force reconnaissance aircrews.

Section II. CONCEPT OF EMPLOYMENT

64. General

The responsibility for staff supervision of the MIBARS lies with the field army G2. He exercises this supervision through his G2 Air.

65. Location

The headquarters and headquarters company, MIBARS usually is located in the vicinity of the field army headquarters. The four military intelligence detachments are dispersed with Tactical Air Force reconnaissance elements, normally squadrons, of the supporting Tactical Air Force reconnaissance wing.

66. Battalion Headquarters and Headquarters Company

a. Functions. The battalion headquarters and headquarters company is composed of elements that provide three separate functions—operations, administration, and logistics. In most instances, the battalion headquarters and headquarters company will be located together, either in the vicinity of the instrumented field army airstrip, field army main CP, or the FATOC. The battalion commander operates from both the battalion headquarters and from the TASE of the FATOC. The operations and intelligence section is located with the battalion headquarters and acts as the focal point for all battalion operations. The imagery interpretation section, reproduction section, and library and reports section are under the operational control of the operations and intelligence section and generally will be located within the battalion headquarters complex. The delivery platoon is also under the operational control of the operations and intelligence section, but normally it is located at the instrumented field army airstrip. One TIIF from the imagery interpretation section is located adjacent to the TASE of the FATOC

and provides the G2 Air element with imagery interpretation facilities and communications means into the MIBARS operations net. The remaining battalion staff and headquarters company elements are located with the battalion headquarters.

b. Peculiarities of MIBARS Battalion Staff.

- (1) The MIBARS S2 is also designated as the S3 operations officer as there is no S3 authorized by TOE.
- (2) The assistant S2 is also designated as an assistant S3 operations officer. He usually will perform duties with the operations and intelligence section.
- (3) The senior air reconnaissance liaison officer (ARLO) normally is located with the Tactical Air Force reconnaissance wing headquarters.

c. Operations and Intelligence Section. The operations and intelligence section is under the direct supervision of the battalion S2. It performs the functions of planning, coordinating, and supervising the battalion's operations and intelligence activities. This section maintains the battalion switchboard and teletype terminals. One image interpreter from this section normally is attached to the senior ARLO as an enlisted assistant. This section provides operational control over the following sections of headquarters company:

- (1) *Imagery interpretation section.* The imagery interpretation section normally is utilized to prepare general imagery interpretation reports (GIIR), mosaics, and other long-range planning functions. One TIIF from this section is located adjacent to the operations and intelligence section to provide communications between the MIBARS detachments

and the G2 Air element at the TASE of the FATOC. The second TIIF in the section is located at the TASE of the FATOC to support the G2 Air element. Both TIIF perform imagery interpretation as directed by the G2 Air or the battalion S2.

- (2) *Delivery platoon.* The delivery platoon delivers reports and imagery, and provides courier service for the MIBARS. It is capable of providing daily delivery of imagery and reports from each reconnaissance airfield to the field army headquarters, corps, and divisions of the field army as required. Normally it is located at the field army aviation strip. If this proves to be impractical or there are no Army airstrips in the vicinity of either the MIBARS or FATOC, then the platoon can be located at the most convenient Tactical Air Force reconnaissance strip.
- (3) *Reproduction section.* The reproduction section receives negatives from the MIBARS detachments for the bulk reproduction of photography. Reproduced copies are delivered to the requester by aircraft or vehicle courier from the delivery platoon. The negatives are then stored by the library and reports section in order to satisfy requirements for additional prints.
- (4) *Library and reports section.* The library and reports section maintains a library of reference materials, negatives, and publications. This section maintains files of reports for use by the MIBARS and other elements of the field army. The length of time imagery is retained will be established by the field army G2.

d. Administrative and Personnel Section. The administrative and personnel section accomplishes all administrative and personnel actions for the battalion, to include handling administrative messages and correspondence.

e. Supply Section. The supply section provides general supply and logistical support to

the battalion, headquarters and headquarters company, and the detachments.

f. Maintenance Section. The maintenance section performs organizational maintenance on the battalion's wheel vehicles. This includes detachment wheel vehicles within the travel limitations caused by dispersion of the detachments to the separate AF reconnaissance airbases.

g. Company Headquarters Section. The company headquarters section performs the command, administrative, supply, and mess functions for the headquarters company.

h. Additional Reproduction Section. An additional reproduction section may be assigned to the battalion based upon an unusual requirement for photography. If the necessity arises, this augmentation could be provided to a separate task force or subordinate headquarters to support a specific operation or long-range requirement.

67. Military Intelligence Detachment, Air Reconnaissance Support

a. The military intelligence detachments usually are deployed with the squadrons of the supporting Tactical Air Force reconnaissance wing. There are four of these detachments in each MIBARS.

b. Occasions will arise when the Tactical Air Force reconnaissance wing will be augmented by an additional reconnaissance squadron. When this occurs, the battalion commander will form a provisional MIBARS detachment which will join the additional reconnaissance squadron. The detachment will be under the command of the imagery interpretation section leader and will be formed with personnel selected from the imagery interpretation, reproduction, administrative and personnel, and supply and maintenance sections.

c. The MIBARS detachment commander performs normal command functions to include providing close supervision over the preparation of imagery interpretation reports and the dissemination of these reports and their accompanying photography.

d. The detachment's ARLO normally is located with the Tactical Air Force reconnais-

MILITARY INTELLIGENCE BATTALION, AIR RECONNAISSANCE SUPPORT

Figure 15. Battalion wire net.

sance squadron collocated at the airfield where the detachment is located.

e. Personnel of the imagery interpretation section normally work in close coordination with the imagery interpreters organic to the Tactical Air Force. When available, common work facilities may be utilized to facilitate handling and interpreting incoming imagery.

f. The detachment normally will receive one set of titled duplicate negatives and two sets of prints for each mission from the supporting reconnaissance squadron. To facilitate rapid interpretation, interpretation can be performed from the wet negative before the prints have actually been made. One of the two sets of prints is used for plotting while the other print is being interpreted. The imagery interpretation section normally confines its efforts to preparing hot and immediate imagery interpretation reports.

g. The reproduction section receives the

negatives from the imagery interpretation section. Reproduction usually is limited to processing current missions. Prints are packaged and made ready for pickup by the battalion's delivery platoon.

h. The detachment is attached for quarters and messing facilities to the Tactical Air Force unit with which it is collocated; however, command, administration, and operational control always remains with the battalion headquarters.

68. Communications

The current MIBARS operations net is discussed in chapter 6. The battalion headquarters also operates an internal wire net as shown in figure 15. Because of the wide dispersal required for individual MIBARS detachments, telephone communication between the detachments and battalion headquarters normally is not possible. A typical MIBARS detachment wire net is shown in figure 16.

Section III. PLANNING AND OPERATIONS

69. Planning

The planning effort of the MIBARS involves a number of considerations.

a. The priority of assignments and the overall workload of the MIBARS are directed by the field army G2 Air.

b. The speed and quality of work accomplished by image interpreters is directly related to the training, specialized area knowledge, and practical experience of the interpreters. Image interpreters require constant training and practice. Therefore, planning the imagery interpretation effort must take cognizance of the skill and experience of the interpreters and includes appropriate area training for these personnel, when possible.

c. Although the photoreproduction equipment is built to function under field conditions, the equipment has fragile components which can breakdown during prolonged operations or improper handling. Consideration must be given for alternate plans in the event of equipment breakdown. The reproduction personnel are trained specialists, but, as with image interpreters, their skill level is commensurate with training, practice, and experience.

d. The deployment of the detachments normally is dictated by the dispersal of the supporting Tactical Air Force reconnaissance elements which may be located anywhere within the theater of operations. The operations of the delivery platoon is affected by detachment dispersal. In some instances, it may be necessary to place aircraft in direct support to a particular detachment due to the time and/or distance factors involved.

e. Weather conditions influence the planning and operations of the distribution effort. Because aerial distribution is largely dependent upon favorable weather conditions, alternate methods of distribution must be planned in event of adverse flying conditions.

70. Operations

The MIBARS operational cycle normally is accomplished in the following steps:

a. An aerial reconnaissance requirement in the form of an air reconnaissance request is forwarded to MIBARS operations and intelligence section from the field army G2 Air. On preplanned requests the full flying data may not be included because it may not always be

Figure 18. Detachment wire net.

ARMY REQUEST NUMBER	TAF MISSION NUMBER	TYPE MISSION	TARGET DESCRIPTION	TOT	TIME NEG REC	RESULTS DESIRED	REPORTS REQUIRED	TIME RPT FWD		TIME NEGS TO REPRO	INTRP BY	PLOTTED BY	DIST. INST.	REMARKS	
								HOT- REP	IIIR						

Figure 18. Imagery interpretation section mission status log.

available when the TACC accepts the mission requirement. On immediate requests, all flying data normally will be included. Upon receipt of either type request, the following sequence of events occurs:

- (1) The duty team in the operations and intelligence section makes the appropriate entries on its mission status board (fig. 17).
 - (2) The operations and sections notifies the appropriate MIBARS detachment of the request. Simultaneously, or as rapidly as possible, the delivery platoon is alerted to the requirement in order that proper flight planning can be accomplished.
 - (3) At the detachment, the commander alerts his ARLO of the pending mission. The ARLO posts his own mission status board, and prepares his briefing notes for the mission. After coordinating the briefing schedule with the reconnaissance squadron, the ARLO instructs the flying crew on the mission's requirements.
 - (4) The MIBARS detachment commander issues a "be-prepared order" to his imagery interpretation and reproduction sections in anticipation of the return of the mission aircraft.
 - (5) The imagery interpretation section posts the requirements on the section's mission status log (fig. 18).
 - (6) The reproduction section prepares the aerial photoreproduction request work order (fig. 19).
- b. Upon completion of the mission—
- (1) The ARLO accomplishes the debriefing of the Air Force flying crew and renders the mission report to the battalion operations and intelligence section.
 - (2) The Air Force photo processing unit develops the raw film imagery. As soon as a wet negative is prepared, it will be given a simultaneous rapid inspection by interpreters from both the Air Force and the MIBARS detachment. This initial check will be only for items to answer the specific EEI of the requester or to identify an item of clearly significant intelligence value. Upon completion of the initial check, the Air Force will produce an additional negative and two prints of the mission for the MIBARS detachment.
- (3) Dependent upon the urgency and priority of the request, the imagery interpretation section may render an immediate imagery interpretation report from the wet negatives which normally will be received before the prints. If this is not required, the imagery interpretation section will perform its interpretation from the negatives and two prints provided.
 - (4) The imagery interpretation section prepares the necessary interpretation reports and furnishes the negatives of the mission to the reproduction section if the request includes a requirement to furnish prints. All reports and prints are dispatched as expeditiously as possible to the battalion operations and intelligence section. Reports normally are transmitted by radio while prints are picked up and delivered by the battalion delivery platoon.
- c. The detachment commander coordinates the entire sequence of events in his detachment to insure proper responsiveness, continuity, and completion of assigned missions.
 - d. Mission reports and imagery interpretation reports are received at the battalion operations and intelligence section where they are immediately disseminated to the field army G2 Air, to the requester, and to other interested agencies as directed.
 - e. Detailed imagery interpretation reports normally are performed by the battalion imagery interpretation section while bulk reproduction requirements usually are accomplished by the battalion reproduction section. Detachments furnish mission negatives to the battalion operations and intelligence section which coordinates the completion of special interpretation and reproduction requirements.
 - f. Initial record and general intelligence record imagery normally is furnished to all tactical Army units having imagery interpre-

tation support that can properly utilize the imagery. Coverage furnished is limited to a unit's area of interest with necessary overlap to insure complete coverage of the area between adjacent units. Reproduction of initial record and general intelligence record imagery is accomplished by the MIBARS headquarters which also stores the negatives for future requirements.

g. Cover traces are prepared by the detachments and are forwarded to the battalion where they are consolidated by the library and reports section. This becomes the master cover trace which is furnished to the G2 Air at field

army, corps, and division. The master cover trace is kept current on a daily basis.

h. Operational requirements may require augmentation of the G2 Air duty teams with the TASE of the FATOC. Should it be necessary to eliminate the G2 Air duty team at the alternate FATOC in order to acquire additional duty personnel, the duties of the G2 Air team at the alternate FATOC can be assumed by the MIBARS operations and intelligence section as an additional duty. Communication equipment required by a G2 Air duty team at an alternate TASE already exists in the operations and intelligence section.

CHAPTER 8

AERIAL SURVEILLANCE COMPANY

Section I. MISSION, ORGANIZATION, CAPABILITIES, AND LIMITATIONS

71. General

This chapter provides general guidance on the employment and capabilities of the Aerial Surveillance Company. FM 30-20-1 (Test) will be utilized as a further reference for detailed guidance on the employment of the Aerial Surveillance Company to include the mission, organization, equipment, capabilities, limitations, command and control, communications, planning, and employment.

72. Mission

The Aerial Surveillance Company provides combat surveillance, reconnaissance, and target acquisition capabilities to corps or division units through the use of organic aircraft, sensor equipment, and ground sensor terminals.

73. Organization

a. General. The Aerial Surveillance Company is assigned to corps and separate task forces, as required. The company is organized under TOE 1-128T (fig. 20). It is a semi-independent unit capable of performing near all-weather day and night aerial surveillance and reconnaissance missions in support of the Corps. The company must be satellited on a higher headquarters for administrative and logistical support. To achieve maximum effectiveness, this unit should be located at an airfield with instrument landing facilities. The commander of the supported unit has operational control of the Aerial Surveillance Company and exercises this control through the ACofS, G2, of the supported unit. The Aerial Surveillance Company is organized with a company headquarters, operations platoon, surveillance platoon, signal platoon, and a

service platoon. The organization provides these functionalized sections to permit efficiency and flexibility of command and employment; however, the organization is not tailored to allow the detaching of separate elements for extended periods of time.

b. Company Headquarters. The company headquarters performs company administration, mess, supply, and organizational maintenance on wheeled vehicles on a continuous day and night basis.

c. Operations Platoon. The operations platoon is the focal point for scheduling, briefing, and debriefing of aerial surveillance missions and for interpreting and reporting imagery information.

(1) *Operation platoon headquarters.* The platoon headquarters provides for continuous flight operations scheduling. Missions are received by the platoon headquarters and checked for completeness. Resources are analyzed and the missions subsequently passed to the surveillance platoon for execution. Flight plans are processed and monitored by the platoon headquarters.

(2) *Imagery interpretation section.*

(a) The image interpreters organic to the company should be located as close to the company processing facilities as possible to insure rapid acquisition of the imagery for interpretation. The specific duties of the imagery interpretation section include all duties listed in chapter 9.

(b) To perform their functions more

Figure 20. Organization chart.

effectively, the imagery interpretation section should receive intelligence summary (INTSUMS), order of battle, prisoner of war, and other intelligence reports from the supported unit intelligence officer on a continuous basis. These reports are used for preparation of imagery reports and to maintain and update the situation map and the intelligence portion of the daily mission briefings.

- (c) The section is organized to man two tactical imagery interpretation facilities (TIIF) in 12-hour shifts. Using the imagery acquired by the surveillance platoon and processed by the photolaboratory section, the imagery interpretation section will produce the reports described in chapter 9.
- (d) Information acquired during interpretation is forwarded to the tasking agency and/or requesting unit by the fastest means available consistent with security classification of the contents and local SOP.
- (e) Telephone and teletypewriter equipment is organic to the TIIF; however, current tables of organization do not provide radios or operators for the TIIF. When radios are not available, imagery reports requiring transmission by radio will be transmitted by the operations section to the requester.

d. Surveillance Platoon. The surveillance platoon consists of—

- (1) *Surveillance platoon headquarters.* The surveillance platoon headquarters provides necessary personnel and ground equipment to establish a small operations section for the platoon.
- (2) *Two aerial radar sections.* Each radar section consists of three SLAR surveillance aircraft plus operators.
- (3) *Four aerial infrared sections.* Each infrared section consists of three IR reconnaissance aircraft plus operators.
- (4) *Fourteen ground sensor terminal*

(GST) teams. In order to provide near realtime readout of SLAR and IR imagery at subordinate headquarters, fourteen ground sensor terminal teams are provided. A GST team consists of a GST for SLAR imagery, a GST for IR imagery, and three airborne sensor equipment operators. Each terminal is mounted on its own vehicle chassis, and includes a trailer mounted generator and a radio for operations within the company command net as well as to provide communications with airborne aircraft.

- (a) All GST receive electronic data input from their associated SLAR or IR sensor aircraft while the aircraft is in flight. This input to the GST is received in the form of a visual display and is also recorded on film to provide permanent record imagery for necessary interpretation. Additional discussion of these GST are contained in paragraph 23c and d.
- (b) The GST teams are provided to support corps and its subordinate tactical elements. Normal employment is to place three teams in direct support of each division in the corps, three teams in direct support of the corps, and one team in direct support of each armored cavalry regiment and separate brigade in the corps. A ground sensor terminal team must work in close coordination with the tactical imagery interpretation facility (TIIF) which is provided to the corps and to the supported units by their attached military intelligence units.

e. Signal Platoon. The signal platoon consists of—

- (1) *Platoon headquarters.* The platoon headquarters exercises supervisory control over the personnel and functions of the platoon.
- (2) *Communications section.* The communications section provides the radio teletype teams that operate the

company radio-teletypewriter sets which are part of the corps military intelligence unit operations net.

- (3) *Avionics repair section.* This section performs organizational maintenance on the avionics, SLAR, and infrared equipment organic to the surveillance aircraft.
- (4) *Three photographic laboratory sections.* The three photographic laboratory sections normally are employed with the company imagery interpretation section to process exposed film for the company and produce photographs as needed. They are responsible to print titling data on all missions. Appendix F prescribes the titling data to be placed on reconnaissance film. Each section is equipped with a photographic darkroom facility which provides rapid, continuous, and automatic processing of exposed film.
- (5) *Camera repair section.* The camera repair section performs all organizational maintenance on the airborne photographic surveillance systems installed on the company mission aircraft.

-f. *Service Platoon.* The service platoon consists of—

- (1) *Service platoon headquarters.* The service platoon headquarters is responsible for the employment of the aircraft maintenance and airfield service sections of the aerial surveillance company.
- (2) *Aircraft maintenance section.* This section performs normal organizational maintenance on the assigned airplanes.
- (3) *Airfield service section.* The primary function of this section is to fuel and defuel assigned aircraft and effect forced entry and rescue from crashed aircraft.

74. Employment

The Aerial Surveillance Company normally will be assigned to and employed in general support of a corps or separate task force. Direct support to subordinate units will be per-

formed on a mission basis. The company also may be assigned to a MAAG or Military Assistance Company to support U.S./host country stability operations. The company performs combat surveillance, reconnaissance, and target acquisition missions for the supported unit. The Aerial Surveillance Company is trained, equipped, and designed to provide the ground commander with current detailed intelligence information of his area of operations and enemy forces within that area. Normally it will be employed as an integral unit at an instrumented airfield within the supported unit's area of operation.

75. Unit Capabilities

a. The Aerial Surveillance Company has the following capabilities:

- (1) Provides sustained near all-weather, day or night, aerial surveillance of a corps area of influence.
- (2) Conducts aerial reconnaissance of routes, zones, and areas using visual, photographic, SLAR, and infrared systems.
- (3) Disseminates the imagery produced by its SLAR and IR systems to various headquarters in near realtime through its ground sensor terminals.
- (4) Processes and interprets the imagery produced by sensor systems and disseminates the information obtained from this imagery and from visual observation.
- (5) Acquires target acquisition information through the use of the above systems.
- (6) Acquires information for poststrike analysis of nuclear weapons effects.
- (7) Acquires information for CBR surveys using aerial means.

b. Personnel of this organization can engage in effective, coordinated defense of the unit's installation. The unit is one hundred percent mobile by utilizing its air and ground vehicles.

76. Unit Limitations

a. The Aerial Surveillance Company must be deployed at an airfield which has instrument approach facilities or it must be aug-

mented with personnel and equipment to provide this capability.

b. The utilization of the ground sensor terminals is limited by the requirement for line-of-sight between the sensor stations and the aircraft conducting a mission.

c. The company has no organic aircraft for command, control, and liaison functions with its detached ground sensor terminals or with

other organizations within the corps area. It also has no aerial delivery capability for imagery interpretation reports and hard copy photography to the requesting units. Other aircraft must be made available to the company for these functions.

d. The company is dependent upon its parent headquarters for personnel and administrative services.

Section II. COMMAND, CONTROL, AND COMMUNICATIONS

77. General

To prevent dissipation of the company's capabilities, definite lines of command and control must be established and maintained.

78. Command

a. Command channels for normal unit administrative, logistical, and maintenance requirements are through the company's parent organization. Training is the responsibility of the company commander with general guidance provided by both the parent organization and the G2 through his principal assistant, the G2 Air.

b. The company can perform normal organizational level maintenance. Direct and general support maintenance will be provided by maintenance units of the corps support brigade as described in FM 29-22.

79. Control

The Aerial Surveillance Company is under the staff supervision of the corps G2 Air. The G2 Air coordinates and integrates the activities of the company with other means of accomplishing aerial surveillance and reconnaissance available to, or in support of, the corps. He directs the company's surveillance effort through the assignment of specific missions and priorities for accomplishment. A G2 Air representative is provided to the company to conduct briefings of the aircrews on mission requirements and debriefings of the crews upon their return. The information obtained is passed to the G2 Air and to requesting headquarters.

80. Communications

a. *General.* Telephone is the normal means of communication within the company area. FM voice radio provides communication between company elements when moving, with higher or supported headquarters, and with mission aircraft for control and coordination of data transmission. UHF voice radio is used for air traffic control. Radio teletype is used to communicate between the company, the parent headquarters, and the Corps G2 Air. When possible, the company enters the corps area communications system for telephone and teletype communications.

b. *Wire.* Telephones are provided to each platoon and subordinate sections or elements requiring communications in the company wire net (fig. 21). The operations platoon headquarters has been provided an additional telephone (not shown on the wire net diagram) for direct communications with the air traffic control element. One teletypewriter and necessary associated terminal equipment is mounted in the company operations van for teletype communications. Wire is provided to install the company wire net, perimeter security net, and trunklines to the area communications system.

c. *Radio.* Radio equipment is provided to meet the minimum requirements of the company. Equipment for remote control operations of radio sets has been included where required. Radio equipment in the company is indicated in the radio diagram (fig. 22).

Figure 21. Aerial Surveillance Company wire net.

*Only one team shown; there are 14 such teams in the company.

Figure 22. Type radio diagram.

Section III. PLANNING

81. General

Aerial surveillance and reconnaissance planning is accomplished as discussed in chapter 5. At the corps, planning will integrate the capabilities of the Aerial Surveillance Company with the capabilities of the aerial surveillance and reconnaissance elements of the other services.

82. Mission Assignment

The corps G2 Air determination of whether a mission will be assigned to the Aerial Surveillance Company, accomplished by other Army aircraft, or by other service support will depend on the following factors:

a. The current operational capability of the Aerial Surveillance Company to perform the mission.

b. The time when the requested information will no longer be of value.

c. The capability of enemy air, air defense, and other countermeasures to prevent organic aircraft from completing their missions.

d. The distance, weather, and terrain between the flying elements and the target area.

83. Concept of Employment

Specific company missions normally are categorized as surveillance or reconnaissance. Additionally, a mission may employ more than one of the sensors organic to the surveillance aircraft. During the mission, the aircraft may change in flight to another type mission, or it may perform a multiple-type mission concurrently.

a. The operations of the Aerial Surveillance Company are characterized by rapid response to mission requirements. This is accomplished by—

- (1) Mission type tasking of the unit to permit maximum flexibility and utilization of resources in obtaining the desired information.
- (2) A capability for rapid response by diversion to other missions in flight, based on changes in the tactical situation, the units supported, or the mission objectives.

- (3) Reliable and secure communications with the G2 Air and the GST.
- (4) Flexibility of mission performance afforded by multiplicity of performance capabilities inherent in the aircraft and in the surveillance systems.
- (5) Acquisition of knowledge of the enemy situation and capabilities by frequent coverage of the same operational areas.

b. In planning the employment of the company's surveillance aircraft, the following must be considered:

- (1) Availability of flying crews, aircraft and sensors, to include previously established priorities and equipment maintenance.
- (2) Enemy air defense capability and locations of enemy units.
- (3) Existing and forecasted weather conditions at the airfield, as well as en route to, and at, the target area.
- (4) Specific results desired; i.e., the type of information the requester wishes to obtain.
- (5) Operational altitude of the equipment in regard to terrain configurations en route to, or in, the target area.
- (6) Aircraft density in the target area and control of air traffic.
- (7) Friendly tactical situation and supporting fires in the target area.
- (8) Tactical air support plan.
- (9) Existing authentication and identification systems.
- (10) Selection of designated landing fields to facilitate direct coordination with supported units. This will include alternate airfields when required.
- (11) Escape and evasion information.
- (12) Aircraft abandonment areas.
- (13) Technical proficiency of pilot, observer, and ground sensor terminal equipment operators.
- (14) Imagery processing, interpretation, reporting, and print delivery requirements and capabilities.

- (15) Coordination with Army Security Agency operations.

84. Briefing and Debriefing

a. General. The Aerial Surveillance Company will be tasked to execute missions involving flight over any or all portions of a corps area of influence. The aircraft crews and company support personnel must be completely familiar with the mission to be flown, must adequately plan and prepare for the mission, and must use prescribed methods of reporting mission data.

b. Briefing and Debriefing of Aircraft Crews. This subject is discussed in detail in chapter 10.

c. Mission Support Personnel Briefing. The company support personnel who will be involved in the conduct of a mission and the processing of mission results also require briefing. Imagery interpretation personnel normally will assist the flying crew in planning the mission and thus are briefed during the planning stage on the information they will need to accomplish the necessary interpretation. The photolab personnel must be briefed on the requirements of each mission, the anticipated processing requirements, and the

deadline for completion of the processing. The ground sensor terminal teams must be alerted to the mission through company communications or by the G2 Air of the headquarters to which they are attached. They will require information on the mission in order to monitor the flight and produce imagery at their stations.

d. Sensor Data Log and Flight Log. A sensor data log and flight log (pilot's trace) are maintained for each sensor mission flown. These are reviewed for completeness during debriefing. It is desirable that the aircrew be present with the image interpreters during the initial readout of the imagery obtained on the mission.

85. In-Flight Reports

To provide commanders and staffs with critical information during the conduct of the mission, the aircrew must be able to make in-flight reports to the requesting unit and other interested elements by means of radio, message drop, or prearranged signals. In-flight reports usually will be rendered during each mission, unless the tactical situation warrants radio silence. Composition and format for in-flight reports are discussed in chapter 10.

Section IV. TECHNIQUES OF AERIAL SURVEILLANCE AND RECONNAISSANCE OPERATIONS.

86. Visual/Photographic Missions

Aerial visual/photographic missions are discussed jointly as aerial camera systems are organic to all surveillance aircraft in the Aerial Surveillance Company. Significant visual sightings normally will be confirmed by photography.

a. The purpose of visual/photographic and surveillance reconnaissance is to obtain information of the enemy and the terrain, and to detect targets. Some of the factors influencing these missions are weather, visibility, altitude, speed of observation, type of aircraft, terrain conditions, type of camera employed, hostile ground fire, and proficiency of the pilot-observer team.

b. Visual and surveillance reconnaissance missions are conducted at an appropriate altitude to permit accurate observation of the

area of interest. Usually the aircraft will fly at an altitude of 1,000 to 1,500 feet above the ground; however, the specific area of interest may require low level observation at nap-of-the-earth altitudes. If low level observation is required, the aircraft should make one pass over the area utilizing any natural terrain features to conceal the approach of the aircraft. If additional passes over the target area are required, they should be made from random directions.

c. Visual/photographic surveillance missions may be accomplished by employing flight teams of two aircraft. This method of employment permits the two aircraft to mutually support each other in their visual observation techniques. Additionally, one aircraft can perform a photographic mission while the other aircraft maintains visual observation over the area of interest. In case an aircraft is downed

by ground fire, the flight team method of employment facilitates rapid recovery of the aircrew.

d. The surveillance aircraft are equipped with a photographic surveillance system employing aerial cameras that can be positioned in flight to provide vertical (with 20% to 80% forward overlap) or side oblique (15° to 30° depression angle) photographs of the terrain. Additionally, some surveillance aircraft are equipped with a fixed-mounted nose camera that provides forward panoramic, horizon-to-horizon photography specifically designed to be taken from low-flying aircraft. This camera takes forward oblique photographs of the ground from forward of the aircraft position out to the apparent horizon, with a 180° coverage forward.

e. Visual aerial surveillance with confirmatory photography becomes especially valuable when the aircrew is familiar with the terrain in the target area. Whenever possible, crews should operate over the same area repeatedly to allow them to become completely familiar with the area so they can recognize and identify changes that take place. In the conduct of repetitive aerial surveillance over areas of interest, however, care must be taken to insure that future tactical operations scheduled for these areas are not compromised by an excessive number of missions over the same location.

f. Techniques used in the accomplishment of visual/photographic missions vary with the tactical situation, enemy strength and disposition, weather and terrain, and are limited only by the imagination of the pilot-observer team. Techniques considered appropriate for the accomplishment of visual/photographic missions are described in (1) through (4) below.

- (1) Reconnaissance of a point target may be accomplished by a flight team of two aircraft. The aircraft approach the target area in a loose echelon formation so positioned that the target area is on the observer's side of the aircraft. Altitude usually will be 1,000 to 1,500 feet above the terrain during the initial observation; if a close reconnaissance of the target is required, the aircraft will fly past the

target and then make a descending turn and execute a low-level, high-speed pass over the target area from a different direction (fig. 23). If photographs are required, one aircraft will overfly the target at the appropriate photo altitude.

- (2) The offset technique can be employed frequently when a single low pass over a target can accomplish the mission (fig. 24). The aircraft approach the target at an altitude of 1,000 to 1,500 feet, and as soon as the target is located in the distance, the aircraft turn away from the target and descend toward a readily identifiable initial point (IP). The route from the IP to the target will be made at nap-of-the-earth altitudes, virtually insuring surprise in the target area.
- (3) Route reconnaissance of a railroad, highway, or waterway can best be accomplished by a flight team of two aircraft. The aircraft fly in a loose echelon formation at an altitude sufficient to clear terrain obstacles, each aircraft positioning itself over opposite sides of the route to be surveyed (fig. 25). This permits observation across the route and under any foliage that might conceal the periphery of the route.
- (4) Aerial cameras organic to the surveillance aircraft have a limited area coverage capability and should be employed only for small target area coverage. The requesting unit should furnish their G2 Air accurate six-digit coordinates of the four corner points of the area from a 1:50,000 tactical map. Upon receipt of these coordinates, the aviation unit can plot the flight traces, considering all the factors affecting the mission. Using the doppler navigation system and the aircraft's autopilot, accurate parallel flightpaths can be flown to produce the required imagery.

87. Airborne Radar Missions

a. Some surveillance aircraft of the Aerial Surveillance Company are also equipped with

Figure 23. Visual/photo point target reconnaissance.

Figure 24. Visual/photo offset technique.

Figure 25. Visual/photo route reconnaissance.

Figure 26. SLAR area search.

Figure 27. SLAR linear coverage.

a Side Looking Airborne Radar System (SLAR). A detailed discussion of SLAR sensor capabilities is contained in paragraph 23d.

b. SLAR is generally employed for large area coverage, as in an area search mission, or in surveillance of linear distances such as traffic arteries, coastlines, and international boundaries. During the conduct of SLAR missions, it is essential that the aircraft be flown in a straight and level attitude. Air turbulence will degrade the quality of the imagery produced. All missions should be flown at the

optimum flight altitude for the recording of SLAR imagery.

c. The following are examples of typical SLAR missions:

- (1) *Area search.* Flightpaths are planned to insure that the target area is continuously being mapped by the SLAR. This can be accomplished by using either a triangular or rectangular pattern as illustrated in figure 26.
- (2) *Coastal or boarder surveillance.* This

mission is executed by flying a course parallel to, and at a standoff distance from, the area of interest. Standoff distances can be varied up to the maximum capability of the system. Throughout the conduct of these missions, in-flight spot reports can be based on target readout from the in-flight processor in the aircraft. Examples of typical SLAR missions are shown in figure 27.

88. Airborne Infrared Missions

a. Additional surveillance aircraft of the Aerial Surveillance Company are equipped with the Infrared Set (IR). A detailed discussion of IR sensors is contained in paragraph 23*c*.

b. The aerial infrared sensor generally is employed to provide air-to-ground infrared coverage of routes, small areas, and suspected enemy locations or installations. The IR system has a day and night as well as a limited poor weather capability, but will not record heat emissions through thick cloud layers, dense jungle canopies, or other similar heat absorbing environments. IR missions usually are executed during the hours of darkness as the natural cooling of the ground permits a larger heat emission differential between "hot"

objects on the ground and the surrounding terrain.

c. The success of night infrared missions is contingent upon accurate navigation to the target area. Consequently, flight planning prior to an infrared mission must be accurate, detailed, and complete. Optimum results from night infrared missions can be achieved by using the doppler navigational system. The coordinates of a readily identifiable terrain feature or manmade feature in proximity to the target area is essential for up-dating of the doppler navigational computer just prior to the imagery run. Utilizing the doppler navigational computer, the pilot can execute the infrared mission by employing parallel or random passes over an area and thus minimize his exposure to ground fire.

89. Multiple Sensor Operations

The surveillance and reconnaissance resources within the Aerial Surveillance Company can be most efficiently employed if the unit is mission-tasked; this permits maximum latitude in the execution of the mission. Thus, the G2 Air representative at the company, imagery interpretation personnel, and the operations officer of the company will be able to plan jointly the use of the most efficient combination of sensors to accomplish the mission within the required time frame.

CHAPTER 9

IMAGERY INTERPRETATION

Section I. GENERAL

90. Image Interpreters

Image interpreters are intelligence specialists trained in the techniques of extracting information from imagery produced by airborne sensors. The image interpreter must know the intelligence requirements of the command in order to quickly identify, locate, and report information obtained from the imagery. Interpreters generally are employed as a group. Normally they are located so as to have immediate access to the film processing facilities serving the various units employing airborne sensors. This assures the availability of adequate interpretation effort at all times, the elimination of administrative dead time in transmitting imagery, and the economical use of processing and interpretation equipment.

91. Duties

The specific duties of image interpreters include the following:

- a. Interpret imagery and report intelligence information regarding the enemy—his operations and activities, disposition, supplies, communications, and installations—and civilian activity related to military operations such as population concentrations, industrial production facilities, and traffic networks.
- b. Analyze terrain.
- c. Evaluate targets for attack by all available weapons systems; prepare target folders and perform damage assessments.
- d. Update maps from current imagery; prepare map supplements from photography.
- e. Prepare mosaics, panoramics, and terrain models for operations.
- f. Assist the G2 Air in planning aerial reconnaissance and surveillance missions.

92. Effectiveness

The effectiveness of an image interpreter is increased by his experience and the amount of background knowledge which he possesses about the enemy and the area of operations. The interpreter's time and effort are also more effectively expended when he is made aware of exactly what information is requested or desired. Effectiveness is enhanced when the interpreter has available to him—

- a. Area studies, other background material, and selected intelligence reports that deal with the enemy and the area of operations.
- b. Operation orders, commander's EEI, and OIR that identify intelligence requirements and the area of interest.
- c. Knowledge of the capabilities and limitations of the supporting aircraft and sensors, and the interpretation equipment available to him.
- d. Knowledge of current enemy tactics, equipment, and order of battle.
- e. Prior imagery of the area of interest for comparative analysis.
- f. Intelligence information received from other sources that will assist in confirming or denying his suspicions.

93. Imagery Interpretation Support

a. *Field Army.* In addition to the imagery interpretation support furnished by the Military Intelligence Battalion, Air Reconnaissance Support, Field Army, the Military Intelligence Battalion, Field Army (TOE 30-25) provides an imagery interpretation section to the field army G2 Air. The primary mission of this section is to support field army operational planning and targeting.

b. Corps. In addition to the imagery interpretation section of the corps Aerial Surveillance Company, the Corps Military Intelligence Detachment (TOE 30-18) provides an imagery interpretation section to the corps G2 Air. Its major mission is similar to that of the imagery interpretation section supporting the field army G2 Air.

c. Division. Each division has an imagery interpretation section which is part of the MI Detachment, Division (TOE 30-17). This section supports the division G2 Air. Its major mission is immediate interpretation of imagery received from the ground sensor terminals of the corps Aerial Surveillance Company which are located within the division area. It also assists in operational planning and target-

ing for division weapon systems.

d. Other Units. Other units having an aerial surveillance or target acquisition capability are provided imagery interpretation support.

- (1) Armored cavalry regiments and separate brigades are provided imagery interpretation support from their attached MI detachments (TOE 30-14).
- (2) Missile commands contain organic image interpreters.
- (3) The field artillery target acquisition battalion is provided imagery interpretation support from within the resources of the MI detachment at corps.

Section II. TACTICAL USES OF IMAGERY

94. General

a. The value of imagery is largely dependent upon the timeliness of the information extracted from it. Items of immediate tactical value can be extracted and furnished to the requester in a relatively short period of time since only a minimum of detailed interpretation and analysis is usually required. Special intelligence studies require a great deal of preparation, research, and detailed interpretation. While the tactical application of imagery is similar at all echelons of the field army, emphasis on its tactical usage will vary with the echelon at which it is used, the tactical situation, and the speed with which the information is required.

b. The primary role of imagery is to provide intelligence information to the commander. Normally this information is provided by the reports furnished by imagery interpretation personnel from the imagery at hand. Because the imagery itself is bulky, requires special storage and protection, and does not lend itself to proper interpretation by untrained personnel, normally it is not furnished to the requesting agency unless there is a particular purpose to be served by doing so. Instead, imagery normally is kept for a reasonable period of time by the imagery interpretation section at the echelon where the imagery interpretation re-

port was rendered and then destroyed (para 104d).

95. Specific Tactical Uses of Imagery

a. Imagery is used to—

- (1) Provide information in response to the commander's EEI and OIR.
- (2) Identify items of immediate tactical significance.
- (3) Assist in operational planning.
- (4) Provide a current, accurate display of an area of interest to the commander to assist him in the tactical employment of his combat troops and his tactical weapons.

b. In providing this assistance, the imagery interpreter utilizes imagery to provide the following types of information:

- (1) *The locations of enemy installations.* These include such installations as missile, artillery, mortar, and automatic weapons emplacements; minefields, barbed wire, obstacles, and strongpoints.
- (2) *Enemy supply installations.* The locations of enemy supply installations and lines of communication. These include forward area supply dumps, rear area supply depots, railheads, transshipment points, and main supply routes.

- (3) *Enemy personnel.* The location of enemy personnel and equipment concentrations.
- (4) *The analyses of terrain.* These include trafficability analyses of terrain for all types of military units and operations, to include road and bridge studies. This use of imagery should not be confused with the detailed terrain studies prepared by Army engineer units.
- (5) *Intelligence information.* The confirmation or denial of intelligence information obtained from other sources or agencies such as order of battle personnel, interrogation of prisoner of war personnel, technical intelligence teams, and clandestine sources.
- (6) *The preparation of target folders.* Image interpreters assist in the preparation of target folders and target information sheets on selected

targets. Target folders may be supplemented by detailed and special imagery intelligence reports or by selected imagery.

- (7) *Damage assessment.* Image interpreters determine the type and extent of damage and its impact upon the tactical situation.
- (8) *Mosaics and panoramas.* Mosaics and panoramas may be used for planning and briefing purposes and for locating and designating targets. Preparation of mosaics and panoramas is time consuming and should be resorted to only when an imagery report or current map coverage will not suffice.
- (9) *Map correction and supplement.* Discrepancies occur between what is shown on maps and what actually exists as shown by aerial imagery. These discrepancies are noted and reported.

Section III. IMAGERY INTERPRETATION REPORTS

96. General

a. The imagery interpretation report formats contained in this manual are compatible with those established in NATO Standardization Agreements (STANAG) Number 2102, Offensive Air Support Operations Message Formats, and Number 3377, Air Reconnaissance Intelligence Report Forms. NATO titles have been changed as indicated below to make them compatible with current U.S. Armed Forces sensor capabilities; however, when these formats are used in operations involving NATO organizations the original NATO title should be substituted for ease of international understanding.

<i>Format title for NATO use</i>	<i>Format title outside NATO</i>
Mission Report (MIS-REP).	No Change.
Hot Photo Report (HOT-PHOTOREP).	Hot Report (HOTREP).
Immediate Photo Interpretation Report (IPIR) -----	Immediate Imagery Interpretation Report (IIIR).
General Photo Interpretation Report (GPIR) -----	General Imagery Interpretation Report (GIIR).

b. The basic types of imagery interpretation

reports are the mission report, hot report, immediate imagery interpretation report, and the general imagery interpretation report. Imagery interpretation reports serve two parallel objectives; they insure the maximum exploitation of information and its timely dissemination to the user. The requirements, preparations, and dissemination of these reports are discussed below and shown in figure 28. While the mission report is designated as an imagery interpretation report, normally it is transmitted by the ARLO or G2 Air representatives who debrief flying crews upon completion of their missions. Mission reports are discussed in chapter 10.

c. All imagery interpretation reports except the general imagery interpretation report follow a prescribed format as to content and organization. This facilitates electronic transmission and insures that the information transmitted is complete and understandable to the recipient. The general imagery interpretation report normally is too voluminous to permit radio transmission. All other imagery interpretation reports normally are transmitted by electrical means. This requires the use of

TYPE	PURPOSE	WHEN PREPARED	PREPARED BY	TRANSMITTED BY	TRANSMITTED TO
IN-FLIGHT	TO SEND FROM THE AIRCRAFT INFO GAINED WHILE IN FLIGHT	AS ORDERED OR AT DISCRETION OF THE PILOT	PILOT	RADIO	REQUESTOR

(CLASSIFICATION)

Figure 30. Hot report.

cise answer to the purpose for which the mission was flown, or to report a sighting of significant intelligence value. The report is rendered as soon as the imagery has been inspected the first time, or immediately upon discovery of a significant item. The report is disseminated to the requester and other interested agencies by the most rapid means available. A HOTREP is not furnished if the ARLO or G2 Air representative's mission report has already been sent and no additional information has been discovered on the imagery. The initial HOTREP should be submitted within 1 hour after the mission aircraft has landed. If during subsequent interpretation a significant finding is made, an additional HOTREP may be forwarded on an immediate basis. Format for a HOTREP is shown in figure 30.

98. Immediate Imagery Interpretation Report (IIIR)

The IIIR is furnished only when specifically

asked for by the mission requester or when the full interpretation of the imagery reveals additional intelligence information not previously reported on the HOTREP or the mission report. The IIIR normally is completed within 4 hours after mission aircraft have returned. An IIIR deals with only one imagery mission, and includes an evaluation of the quality of the imagery and area coverage accomplished. Format for an IIIR is shown in figure 31.

99. General Imagery Interpretation Report (GIIR)

The GIIR is designed to provide detailed intelligence information in response to a specific request, primarily to assist in planning future operations. It may be made from a new mission specifically flown for the requirement, or from existing coverage. No special format is used; the content will vary according to the requirements of the information being reported. Reports are submitted to meet the time limitations imposed by the requester.

Section IV. TARGET FOLDERS

100. General

Supervision of the intelligence aspects of an air target program is the responsibility of the G2 Air. To assist him in this function, imagery interpretation personnel provide intelligence information taken from aerial imagery that can be used in compiling target folders. Once a potential target has developed to the point where it is a suitable target for employment of a weapons delivery system, the G2 Air will recommend its inclusion among those targets selected for attack.

101. Target Folders

Before a target can be selected for attack, the type of target must be determined—its composition, strength, vulnerabilities and permanency—to allow for the selection of an appropriate weapons system to be employed. A target study requires the collection and evaluation of many items of information all of which ultimately will add up to the identification or elimination of an actual target. The G2 Air and image interpreter use the target folder to compile the necessary information. A major

prerequisite for starting a target folder is the relative degree of permanence of the potential target. Transitory targets must be selected for attack by employing methods other than the target folder.

102. Contents of Target Folder

A target folder should be maintained on all potential targets. The composition of the folder will vary with the type of target but should contain as a minimum—

a. A target folder index of items contained therein.

b. A target worksheet which includes a target designation, description, location, and any other special intelligence information. It should also include the source and evaluation of the information, the date of confirmation, and all agencies who have been, or will be, furnished the information.

c. A target information sheet which contains a detailed listing of physical characteristics of the target to include separate elements of large or "hard" targets such as large supply facilities or multiple-building complexes,

the significance of the area as a military target, obstructions to low flying aircraft in the area, and defenses around the area to include air defense measures.

d. A target illustration sheet which nor-

mally consists of an annotated photograph of the target area.

e. Any additional target information not included elsewhere.

Section V. SECURITY CLASSIFICATION OF AERIAL IMAGERY

103. General

Aerial imagery is classified according to the degree of classified information that it contains or according to the methods by which it was obtained. The determination to classify imagery according to content, and the degree of classification selected, is the responsibility of the commander of the area over which the imagery has been taken. In actual practice, the area commander will designate the classification procedures; however, the unit that controls the sensor equipment will be responsible for marking the imagery produced. Security classification of imagery will always be accomplished in accordance with AR 380-5 and AR 380-6.

104. Marking, Storage, Control, and Destruction of Classified Imagery

a. Actual marking of imagery is governed by the method in which it is handled and stored.

- (1) Negatives and prints in uncut rolls need only be marked with the classification at the beginning and end of each strip.
- (2) Negatives and prints that are cut must be marked individually. Individual negatives and prints must be marked top and bottom on each copy. In addition, the classification should be placed beneath the legend (title block) of each negative, and in the center of the reverse side of each print. Negatives must be marked so that the classification will reproduce clearly on all copies made.

b. In addition to marking negatives and prints, all containers and wrappers used to store classified imagery must be conspicuously marked in compliance with AR 380-5. The storage of classified imagery is no less impor-

tant than for other classified documents. Under conditions of 24-hour operations, large volumes of classified imagery can be secured by keeping it under the physical control of the duty team.

c. Classified imagery will be furnished only to those who possess proper clearance and have a need-to-know. Receipt and registration requirements are the same as for other documents.

d. Destruction of classified imagery is the same as for other classified documents. With imagery, bulk destruction is a normal but a time-consuming process. To facilitate destruction procedures and eliminate keeping excess imagery on hand, all echelons should establish a periodic imagery review program to identify imagery no longer required so that it may be destroyed or furnished to other interested agencies. Local SOP will establish imagery retention periods; however, the tactical value of imagery normally will have been fully exploited within 90 days after acquisition. This period will be shortened or lengthened dependent upon the degree of tactical movement taking place in the combat area, and the echelon of command at which the imagery is being retained.

105. Derivative Classification

Reports and special studies developed from classified imagery and referring directly to that imagery will require a derivative classification at least equal to the classification of the imagery itself. Individual items of information contained in the report which would require a higher classification would be an overriding factor in the final selection of the overall classification of the report or study. When the final classification is made on a derivative basis only, group markings must correspond to the group markings of the imagery.

CHAPTER 10

BRIEFINGS AND DEBRIEFINGS

Section I. GENERAL

106. Purpose

Briefings and debriefings are conducted for all aviators, aerial observers, and airborne sensor operators as a means of insuring the most effective utilization of available aerial surveillance and reconnaissance means.

107. Briefings

Briefings serve the purpose of furnishing flying crews a thorough understanding of current enemy and friendly situations, the terrain and weather, the requirements of the assigned missions, and other administrative instructions that facilitate the successful accomplishment of their tasks. Briefings by Army ARLO or G2 Air representatives may be given separately or as a part of a unit briefing presented by the commander of the Army or Air Force unit providing the supporting aircraft.

108. Debriefings

Debriefings of flying crews are conducted to obtain from crewmembers any information of

intelligence value which they have acquired during the course of their mission. This information may be in addition to that which they have collected by an airborne sensor means, or it may confirm or refute information indicated on their sensor returns. Debriefings are conducted immediately upon return of a flying crew. Many times items of significant interest will be identified through debriefing long before the sensor results have been processed and interpreted.

109. Conduct of Briefings and Debriefings

All briefings and debriefings discussed in this chapter are limited to those presented by the attached ARLO or G2 Air representative present with a flying unit. When possible, debriefings are conducted by the same person who conducted the briefings. These briefings and debriefings do not replace unit briefings conducted at the discretion of the commander of the flying unit.

Section II. BRIEFINGS

110. General Briefing

a. The ARLO or G2 Air representative general briefing normally is given on a daily, pre-planned basis to all flying crews of the flying unit. Usually it is presented as part of the flying unit's daily briefing. The unit's daily briefing includes presentations by the unit commander, the operations officer, the intelligence officer, the weather officer, and other specialists and technicians as directed by the unit commander. The general briefing of the G2 Air representative or ARLO acquaints fly-

ing personnel with the current (next 24 hours) operations, the enemy and friendly situation, terrain and weather, and administrative instructions. This general briefing aids in reducing the amount of information which must be presented at a preflight briefing.

b. The information presented by the ARLO or G2 Air representative in the general briefing follows the format of a standard operation order (fig. 32). Items in an operation order such as weather, administration or logistics can be eliminated by the ARLO or G2 Air

BRIEFING GUIDE

Figure 32. Briefing guide.

representative when covered by other briefers. As a minimum, subjects which should be covered in the general briefing include—

- (1) *General summary of the situation.*
 - (a) Current friendly and enemy activity.
 - (b) Resume of enemy order of battle.
 - (c) Current estimate of enemy's capabilities and courses of action.
 - (d) EEI and OIR.
- (2) *Terrain in the area of operations.*
 - (a) Location of critical terrain features.
 - (b) Location of possible enemy assembly areas.
 - (c) Identification of enemy lines of communication.
 - (d) Location of possible traffic choke points.
- (3) Discussion of the supported unit's aerial surveillance and reconnaissance plan.

111. Preflight Briefings

A thorough understanding of the aerial surveillance or reconnaissance mission to be performed enhances mission accomplishment by the aircraft crew. The ARLO or G2 Air representative preflight briefing is conducted to provide flight crews with the latest information concerning the purpose and importance of their mission, problems which may be encountered, and specific information desired by the requester. The preflight briefing is more specific than the general briefing. Time allotted for preflight briefing will vary from a few minutes on an immediate mission to as much as 30 minutes for a preplanned mission. The briefing may be by the ARLO or G2 Air representative alone, or it may be given in conjunction with the preflight briefing presented by members of the flying unit. It may even be necessary to provide preflight-type briefing information to an aircraft crew in flight, should an adjustment be made to their current mission or an actual diversion be made to another mission. Items covered include—

- a. Mission requirements.
 - (1) Identification of requesting unit.
 - (2) Mission priority.
 - (3) Type of mission.

- (4) Location and description of target and target area.
 - (5) Time on target (TOT).
 - (6) Specific intelligence requirements.
 - (7) If a photomission, type of coverage and desired scale.
 - (8) Coordinating instructions, unit call signs, preplanned fires, and rendezvous instructions.
 - (9) Frequencies and call signs for lifting supporting fires.
 - (10) Requirement for confirmatory photography, when appropriate.
 - (11) Requirement for in-flight reporting, when appropriate.
- b. Changes in friendly and enemy dispositions since last general briefing.
 - c. Special checkpoints and other navigational aids.
 - d. Possible enemy countermeasures en route to, from, and in the target area.

112. Briefing Materials

a. Current information required to present accurate ARLO or G2 Air representative briefings is received through Army channels. ARLO normally receive their briefing material through their parent MIBARS organization. This consists usually of an ARLO packet developed by the field army G2 Air duty team and delivered through the MIBARS operations and intelligence section by the battalion's organic delivery platoon or over the MIBARS operations net. G2 Air representatives receive current information from their own G2 Air section. This information normally is transmitted by signal communication means as discussed in chapter 6, or is delivered by scheduled courier runs. In addition, operational traffic on the MIBARS operations net or command intelligence net will furnish current information of briefing value.

b. To provide a rapid means of presenting preflight briefings on the most current information readily at hand, the briefing officer will require various briefing aids. The major aids to be maintained include—

- (1) Situation maps to present both the enemy and friendly situations and show the areas for specific missions.
- (2) Aerial photographs to familiarize air crews with terrain features, the tar-

get area, and possible target locations.

- (3) Files and records for ready reference, to include intelligence reports, operation orders, order of battle, and special studies.
- (4) Identification keys to orient flying personnel on new equipment, or to

assist in debriefings by identifying objects sighted.

- (5) Any other graphic aid which will increase the flying crews' recognition and retention capabilities. Examples are terrain models, special photographs, sketches, and models of various types of equipment.

Section III. DEBRIEFINGS

113. Purpose

Debriefings are an important part of the ARLO and G2 Air representatives' duties. The purpose of debriefings is to insure the collection of the maximum amount of usable information and to allow the dissemination of this information in the minimum amount of time after aircraft touch down. If the flying crew makes an in-flight transmission of information via the spot report receiver system, or over a prearranged frequency direct to the requesting unit, it should also be discussed in the debriefing for possible additional information. In-flight reports are included as part of the debriefer's mission report.

114. Planning Debriefings

To facilitate accomplishment of a debriefing, the use of aids should be preplanned. Items such as maps, special photography, models and other aids which will assist flight crews in recalling observations should be made available. A debriefing checklist of a format similar to figure 33 is used to keep a debriefing moving smoothly and to eliminate gaps in the information given or needless duplication of comments. When required for specific intelligence purposes, debriefers must plan to bring in specialists or technicians, such as image interpreters, technical intelligence specialists and other qualified intelligence specialists, to assist in debriefing by asking questions within their specialized areas.

115. Conduct of Debriefings

a. Debriefings normally are conducted in coordination with the flying unit's intelligence officer. They are conducted informally and with

due consideration for the physical and mental fatigue of the flight crew. Each crewmember normally is debriefed individually. Debriefings generally are conducted without interruption. Items developed that have significant value immediately should be transmitted as HOT-REPS. When possible, debriefings should be recorded to assist in developing the complete mission report after the debriefing is completed.

b. In the debriefing, each crewmember describes in his own words the mission and his observations or findings. The debriefer asks questions to clarify statements or guide the crewman in his narrative. The debriefer must establish rapport with the crewmember to be effective. He must rely upon his own personality and acquaintances with the personnel of the flying unit to put the crewmember being interrogated at ease. The debriefer should be accepted as an equal by the crewmembers; his periodic performance of surveillance missions as a regular crewmember will assist in his acceptance and will allow him to better understand the problems, capabilities, and limitations of flying personnel. Before the debriefing is terminated, both the crewmember and the debriefer should review the notes taken for completeness and accuracy. The debriefer should not—

- (1) Ask leading questions.
- (2) Discredit the crewman's observations or beliefs.
- (3) Be overly insistent in questioning.
- (4) Argue or introduce needless discussion.
- (5) Keep a briefing going longer than is necessary.

Section IV. RECORDS AND REPORTS

116. Records

All ARLO and G2 Air representatives maintain records to assist in the performance of their duties and serve as references for future operations and periodic resumes of operational accomplishments. The minimum records maintained include—

- a. Daily Journal (Reference FM 101-5).
- b. Aircraft and sensor equipment status record.
- c. Current planned, in-flight, and completed missions.
- d. Operation orders and intelligence reports.
- e. Current briefing notes and aids.
- f. Completed reports and action summarizations.

117. Reports

a. *In-Flight Report.* The in-flight report is transmitted by an aircraft crew during the conduct of a mission as soon as they are able to report the results of their mission, or to report tactical information of such importance and urgency that delay in reporting would render

the information useless. The report is transmitted by voice radio, in the clear, unless prearranged codes have been established. The format for the in-flight report is standardized and shown in figure 34. It complies with NATO Standardization Agreements (STANAG) Number 2102, Offensive Air Support Operations Message Formats, and Number 3377, Air Reconnaissance Intelligence Report Forms.

b. *ARLO and G2 Air Representative Reports.* Three types of reports normally are submitted by ARLO and G2 Air representatives. Additional reports may be required by the supported G2 Air or the MIBARS element commander as the situation dictates. The three common reports are—

- (1) *Hot report (HOTREP).* This report is a short, concise report covering significant information of immediate tactical value (para 97). Normally it is disseminated as a result of receipt of significant items of information during a debriefing. The HOTREP format is standardized and as shown in figure 30.

TRANSMITTED BY VOICE RADIO	
FORMAT (NOT TO BE TRANSMITTED)	EXAMPLE MESSAGE
<p>INFLIGHT REPORT: ALWAYS START OF MESSAGE.</p> <p>AIR TASK/MISSION NO.</p> <p>A. LOCATION IDENTIFIER (ONLY IF NECESSARY FOR CLARIFICATION)</p> <p>B. TIME ON TARGET/TIME OF SIGHTING.</p> <p>C. (CLASSIFICATION)

Figure 35. Mission report.

- (2) *Mission report (MISREP).* A mission report is submitted at the conclusion of each mission. It is based on the notes and observations made during the debriefing and includes any in-flight report made by the aircraft crew and any HOTREP sent by the debriefer while conducting the debriefing. Preparation and dissemination of mission reports is accomplished as rapidly as possible after completion of the mission and normally not later than 30 minutes after aircraft touchdown. The format for a mission report is standardized and is shown in figure 35.
- (3) *Summary report.* The summary report is a consolidation of information on selected enemy activity and is submitted to the G2 Air according to the schedule which he establishes. These

reports are used by the G2 Air to analyze the enemy situation, the effectiveness of the aerial reconnaissance and surveillance effort, and to assist in planning future operations. Format will vary with the requirements of the report.

c. Dissemination of ARLO and G2 Air Representative Reports.

- (1) The normal dissemination of ARLO reports is through the MIBARS headquarters to the G2 Air. The ARLO transmits his HOTREP and mission reports over the MIBARS operations net or uses the delivery platoon to the Operations and Intelligence Section of the MIBARS. At the MIBARS the report is simultaneously disseminated to the G2 Air duty team and other interested agencies as directed. The sum-

mary report is transmitted to the G2 Air in the same manner. Copies of all ARLO reports at detachment level are furnished to the detachment commander for his information and to assist the detachment's imagery interpreters in the accomplishment of their mission. His reports may be transmitted in conjunction with imagery interpretation reports on the same mission if no time delay

- will be involved.
- (2) The G2 Air representative normally will use either radio, telephone, or courier to send his reports directly to the G2 Air. Copies of his reports are furnished to the flying unit and imagery interpretation personnel concerned with interpreting the imagery obtained as a result of the same mission.

CHAPTER 11

AERIAL SURVEILLANCE AND RECONNAISSANCE IN STABILITY OPERATIONS

Section I. GENERAL

118. Introduction

Methods and techniques of aerial surveillance and reconnaissance in stability operations are basically no different than for any other type of warfare, although their scope is broader. The surveillance watch in stability operations is extended over the entire area of interest, possibly the entire host country, rather than limited to an immediate battle area. Except for this enlarged area of coverage, all other doctrine for aerial surveillance and reconnaissance remains valid.

119. Special Considerations

a. The effectiveness of aerial surveillance and reconnaissance in populated areas is decreased because insurgents mingle with the populace and blend with the civilian environment. All villagers cannot be assumed to be insurgents, or treated as such, simply because they live where insurgents are active. Thus, insurgents become much more difficult to identify. Techniques of aerial surveillance employed, therefore, will vary with the degree of loyalty of the people to the government and with the degree of insurgent pressure on the area. Valuable information is derived from watching the actions of the people. Any variation from their normal pattern of living, or the presence of people in areas where they normally are not found, is reported as quickly as possible.

b. Elements of the insurgent village militia are much more difficult to detect and identify than the elements of local and main force units because—

- (1) The insurgent village militia attempt to remain indistinguishable from the general public by taking on the ap-

pearances, habits, and common practices of the people of the area in which they are operating. They are, in fact, usually indigenous to these areas.

- (2) In most of their activities they normally remain dispersed to avoid detection, and to minimize their value as a military target.

c. All insurgents can still be detected, however, through indirect, as well as direct, evidence of their presence. Direct evidence—such as easily recognized uniforms, equipment, military-type vehicles, deliberate field fortifications, logistical facilities, and large troop movements—normally is difficult to gather in stability operations. Indirect evidence of insurgent presence are most probably the indicators which will be first discovered. Examples of indirect evidences are—

- (1) Ostensible civilian activity in isolated areas or in areas where activity normally has not been observed.
- (2) Unexplained increases in the dwelling density of a village.
- (3) Builtup areas not shown on official maps or which are first detected as a result of comparative photography of the area.
- (4) Unexplained movement of local inhabitants from one location to another or across international boundaries.
- (5) Unexplained abandonment of villages, cultivated areas, equipment, or food sources.
- (6) Isolated open areas being prepared for, or under cultivation with, food crops or small areas of forest being

cleared of underbrush and thick foliage for no apparent reason.

- (7) Logging, charcoal, and other rural-type production in areas previously unworked or not easily accessible to people of the area.
- (8) Roads, cart trails, and footpaths that are inconsistent with population centers and the agricultural practices of the area.
- (9) Other unexplained disturbances to the normal vegetative cover of the area.
- (10) Fires in remote areas or burned out areas that have not been caused by local ground clearing operations or indigenous cultivation.
- (11) Fishnets located in isolated areas or areas previously unfished.
- (12) Abnormal increase in traffic on established roads or waterways.
- (13) Unidentified or suspicious activity detected by IR, radar, or other sensory devices at night or during bad weather.

d. Adverse weather places limitations on all aerial surveillance and reconnaissance means. When the weather permits observation by airborne means, insurgents usually will act in a way that makes their presence unknown. When the weather precludes normal aircraft operations, the insurgent force will move and strike more openly. Because weather conditions change rapidly, airborne surveillance measures are preplanned so they can be implemented as soon as the weather conditions permit. In this way insurgent forces are exposed

or caught in activities they reserve for periods when they think they cannot be observed.

120. Requirements for Effective Aerial Surveillance and Reconnaissance

a. Aerial surveillance and reconnaissance is required throughout all phases of insurgency. Requirements differ at each level—national, subnational, and tactical unit—according to the particular phase of insurgency involved. When more than one phase is in effect simultaneously, aerial surveillance and reconnaissance requirements become more numerous, complex, and varied than in single-phase situations.

b. The role of aerial surveillance and reconnaissance in stability operations is much broader than in other types of warfare. Since the enemy normally does not occupy fixed positions or fixed terrain, locating him will depend in large part on the full utilization of the capabilities of the collection means that are sent out to locate him. To preclude stifling this capability, it is important that missions assigned to aerial surveillance and reconnaissance elements are broadly stated to allow maximum initiative and responsiveness to changing situations.

c. By close coordination and cooperation, the intelligence officer makes certain that aerial surveillance and reconnaissance is integrated into the overall collection plan supporting the stability operation. Further, he coordinates closely with sources of information other than intelligence collection agencies. This includes host country civilian, paramilitary, and military agencies, and U.S. and allied military and civilian organizations in-country.

Section II. AERIAL SURVEILLANCE AND RECONNAISSANCE OPERATIONS

121. General

General considerations in planning, operations, and coordination of aerial surveillance and reconnaissance as described in this manual remain valid for stability operations. However, the capabilities and responsiveness of aerial surveillance and reconnaissance agencies, equipment, and types of missions will be affected by the unique environment of stability

operations as discussed in the following paragraphs.

122. Visual Aerial Surveillance

a. Visual aerial surveillance generally is the most responsive means of aerial surveillance available in stability operations. Insurgent activity is identified from repetitive visual area search which brings the observer into daily

contact with assigned areas of interest. It is most important that the pilot and observer remain assigned to the same area as long as possible. By looking at the same area on the ground, the same manmade objects contained there, and the same human activities that take place there day-after-day, these trained personnel will detect changes in the topography of the area and the daily life of the people. Sightings can be reported while a mission is in progress without having to wait for mechanical processing, development, or lengthy interpretation. Both the Army observer and the Air Force forward air controller are important members of the visual aerial surveillance team. Army and Air Force forward air controller's aircraft are the best means of visual surveillance since "low-slow" type of repetitive coverage is required to seek out and discover the indirect indicators which point to insurgent presence in an area. High altitude, supersonic, long-range visual reconnaissance aircraft are better suited for more conventional-type targets possessing sufficient detail and identifiable characteristics.

b. A special employment of visual aerial surveillance in stability operations is the use of continuous day-night visual observation over friendly installations. Insurgent attacks against installations usually involve the use of mortars and recoilless rifles as well as demolitions and individual weapons. The employment of crew-served weapons requires the selection and preparation of weapons positions, fields of fire, and the stockpiling of ammunition in advance of the attack. To accomplish this preparation, the insurgent must infiltrate under-cover into the selected areas which surround the installation. Continuous, visual aerial surveillance out to the maximum effective range of the weapons available to the insurgent may disclose any unusual movement taking place within the area, or even the actual preparation of firing positions.

123. Permanent Record Imagery

a. *Photographic Imagery.* The most valuable of the different forms of imagery available is photographic coverage. Aerial photography provides a permanent, highly accurate picture of an area of interest. Night photography is possible by using artificial illumination. The

greatest value of night photography is the evidence it can record on targets such as field fortifications, vehicles, or clandestine water traffic at sea and on navigable rivers. The disadvantage of artificial illumination is that it shows the insurgent that there is an interest in his immediate area and that photographs of him and his surroundings have been taken. Unless adversely affected by weather or lack of natural or artificial illumination, photography enhances the probability for detection and identification of both direct and indirect indicators of insurgent activity more than do other forms of permanent record imagery now available.

b. *Radar Imagery.*

(1) Moving target indicator (MTI) radar imagery has an important role in stability operations.

(a) Radar sensory equipment is particularly valuable if an insurgency moves into phases where more conventional military operations predominate. It detects insurgent movement in vehicles or other carriers under most weather conditions. It makes possible repetitive surveillance of open seas and navigable waterways and also across international borders where the insurgent forces may operate motor vehicles and aircraft. Under ideal conditions radar sensors may locate the movement of pack animals; however, the slow speed of these animals makes them very difficult to detect.

(b) There are limitations to the use of radar in stability operations. Radar imagery for area search missions during periods when visual and photographic coverage is unobtainable may have only marginal value due to the types of likely insurgent targets, i.e., hidden trails, small camouflaged supply caches, personnel moving under jungle cover singly or in very small groups, etc. In stability operations, particularly in Phase II of the insurgency, the principal target is the insurgent guerrilla and airborne radar is not

an efficient detector of a man or small groups of men. It also does not identify the indirect indicators which are prevalent in insurgency. Unless there is clearly defined terrain inside which all MTI radar returns can be considered hostile, the effectiveness of radar in the early stages of insurgency is limited.

- (c) Unlike photography or visual sightings which can more readily identify an indicator as insurgent or friendly, radar will report friendly or neutral indicators with the same degree of "truth" as it reports enemy indicators. Therefore, all detections are confirmed or refuted by other intelligence to ascertain that the objects detected are, in fact, of insurgent origin. To help solve this problem, specific areas of terrain and bodies of water can be declared "off-limits" to the populace through coordination with the host country. Once the "off-limits" areas have been established, they are scanned with radar for movement or changes in the cultural patterns. Any disruption to the normal patterns in the area is considered an indication of insurgent activity and, depending on the degree of identification achieved, either further investigated or attacked by friendly elements immediately upon detection. Such a program involves close coordination between air-ground elements and other services; it also requires accurate in-flight interpretation from radar screens and good communications for immediate reaction to detected activities. As a general rule, radar surveillance is established where insurgent movement is expected to occur in the degree necessary to register on the sensory equipment and visual and photographic coverage have been rendered ineffective by adverse weather or lighting conditions.

- (2) Fixed target information (FTI) radar can provide a readily available and accurate mapping source and should be used over areas not previously mapped, or where maps are found to be highly inaccurate. Mapping coverage can be obtained during periods of poor visibility or bad weather. Extremely bad weather, however, will reduce the effectiveness of radar. While the small scale of radar mapping precludes its use when great detail is required, it does afford an up-to-date, constant scale reproduction of the physical characteristics of the terrain.

c. *Infrared Imagery.*

- (1) Infrared (IR) can be used with a certain degree of effectiveness in stability operations, regardless of the use of photographic coverage. Currently IR is best used as a passive night surveillance system, since its use cannot be detected from a ground position. Imagery received from IR is not as refined as photographic imagery, but it does provide usable intelligence information. As in photographic surveillance where the development of comparative cover allows an interpreter to identify even the more subtle changes that take place in an area, the examination of comparative IR imagery enables interpreters to detect changes in the pattern of heat emissions.
- (2) Photographic and IR imagery are complementary. For example, if a possible base camp area has been identified on photography, IR can be used to attempt to record heat emissions from cooking fires, supplies, and any pack animals within the area. However, poor thermal conditions and dense jungle canopies will attenuate thermal emissions before they reach the airborne sensor detector.
- (3) Insurgent forces will attempt to defeat IR sensors by "hiding" their own sources of thermal emission. Cooking fires are either built during the day when the surrounding ground is

much warmer, buried beneath rocks and layers of dirt that dissipate the heat released, or at a distance from the actual encampment. Additionally, insurgents may practice stringent fire discipline to the point that often only one fire will be allowed and a single individual will cook all the food for his entire group. In some instances, they build "dummy" fires away from the actual encampment to confuse collection and evaluation efforts. Supplies and equipment are often buried or hidden inside caves and underground tunnel complexes so that their emissions cannot be detected. Therefore, negative results from an IR mission alone should not be considered proof that an area is unoccupied or not being used by insurgent forces.

- (4) An additional disadvantage of IR derives from the low levels at which aircraft carrying IR equipment must fly. (The operational altitude selected will depend to a great extent on the actual terrain and type target being flown over (see TM 11-5850-218-12).) Aircraft may not be able to fly low enough to make sensors fully effective over mountains and dense jungle, which often will be prevalent in stability operations. When forced to operate above optimum altitudes, the quality of IR imagery will be affected adversely. Problems also may be encountered in locating accurately the actual ground coverage of an IR mission when these missions are conducted over the type of unmarked terrain often encountered in areas of stability operations.
- (5) In the early phase of insurgency, the principal use of IR is to help confirm or deny possible insurgent activity reported by other intelligence sources. Potential insurgent areas can be recorded on permanent IR imagery for future comparison. As the insurgency progresses, the use of IR is expanded to include potential routes of insurgent movement, known and possible

base camp areas and safe areas, and border-crossing points for men and equipment. As insurgent tactics, unit composition, equipment, and transportation become more conventional, IR is more fully utilized in its conventional roles.

124. Permanent Record Imagery Coverage

a. Scale of Coverage. As a general rule, the scale of permanent record imagery should be the largest possible, consistent with the type of coverage desired, intended use, size of area to be recorded, time allocated for the mission, the type of aircraft and sensor mode available, and the degree of urgency of the information desired. In stability operations where much of the country is often jungle or densely forested, the ability to "see" between (vertically) or underneath (obliquely) thick vegetation will be directly affected by the scale of the imagery. But large-scale imagery has certain undesirable characteristics which also must be considered. These are the increased aircraft time required over the target area and the larger amounts of imagery which will be required to cover the target area, necessitating either additional time for interpretation or the assignment of additional interpreters to accomplish the mission. The scales recommended below vary from those recommended in chapter 4 due to the special factors of stability operations.

b. Categories of Coverage.

- (1) *Initial record.* In stability operations, initial record coverage often includes international borders and adjacent areas inside all neighboring countries as can be accomplished without an unauthorized violation of the international boundaries of friendly or neutral nations. Coverage also includes likely insurgent routes into the host country and the location of potential or actual safe areas, tactical airfields, motor transportation, and logistical storage areas located within and outside the borders of the host country. Initial photographic record coverage can serve as a map substitute or supplement. It provides information about cultural features, traf-

ficability, soil and vegetation, and when visible, enemy installations and defenses. Scale of this imagery should be between 1:10,000 and 1:25,000. Areas which have seasonal changes will require photographic updating on that basis. Photography of any area that shows a permanent change in cultural features is also updated. All initial record imagery provides a basis for comparison with subsequent imagery received. Initial record coverage should be completed at as early a date as possible.

- (2) *General intelligence record.* The scale for this type of photography should be between 1:5,000 and 1:10,000. The primary use of general intelligence record imagery is to determine changes which have occurred in the basic information developed from the initial record, and to evaluate these changes properly through detailed imagery interpretation. Other major uses are to develop studies on landing zones, drop zones, and the trafficability of roads, cart tracks, trails, and footpaths; and for use as map supplements and photomaps for current operations, especially those involving patrolling, search and destroy operations, clear and secure operations and other tactical operations in inhabited areas. The value of the general intelligence record for target acquisition and poststrike damage assessment is limited due to scale, the size of the area to be covered, and the general lack of large targets. However, it is valuable in the development of annexes on terrain, trafficability, cultural patterns, and general insurgent activity for current intelligence estimates. This coverage is not flown on a periodic basis, but rather over specified areas when required by current or planned operations, or to assist in the intelligence collection effort of that area. Target folders of friendly installations, used extensively in reaction force planning and

operations in support of this installation, include this kind of imagery as well as terrain, trafficability, and defense overlays developed from a study of the imagery.

- (3) *Detailed intelligence record.* This is very large scale imagery, 1:5,000 and larger, flown to cover pinpoint targets or small areas of specific interest. It supplements the general intelligence record, secures better coverage of areas which have become suspect as a result of the interpretation of general intelligence record imagery, or is used to attempt to confirm or deny information gathered from other sources. Its greatest value is in registering small targets or isolated indicators which cannot otherwise be confirmed or denied. It is very useful in pinpointing coordinates of insurgent targets and for poststrike analysis. Because of its large scale, imagery interpreters can better locate individual activity, isolated caches, and defenses that consist of only one or two foxholes or a single weapons emplacement. Camouflaged objects such as cave entrances, supply caches, training areas, and mockups may be located and identified. At these scales such activities as charcoal making, slash-and-burn activity, and hut, lean-to, and elevated OP construction can be identified. Use of pack animals, animal-drawn wagons, or hand-cart activity may also be discovered. Vertical and oblique photography should be requested for such targets to insure complete coverage; special detection devices such as color photography and camouflage detection film should be used whenever possible. Large-scale photography is quite valuable in prisoner interrogation. Good photography can overcome language barriers and allow the individual being questioned to pick out things which he can identify, and thereby furnish more accurate and detailed information.

Section III. IMAGERY INTERPRETATION

125. General

While hot reports and immediate imagery interpretation reports continue to serve specific intelligence requirements in stability operations, there is concurrently an increased need for the more detailed general imagery interpretation reports. These reports are of greatest value to the requester who needs information on terrain characteristics, trafficability, road and trail reports, landing and drop zones, or other items which require extensive interpretation, evaluation, and measurements. In most instances, these reports include the preparation of overlays and other graphic displays such as photomosaics, annotated photography, and target surveillance folders.

126. Image Interpreter Support

In stability operations, national, subnational and area coordination centers normally will have imagery interpretation support. This support will consist usually of host country imagery interpretation personnel advised and assisted by U.S. Army image interpreters. In addition, all U.S. Army aerial surveillance and reconnaissance elements participating in stability operations will have interpreters available, as will military intelligence units supporting U.S. Army ground units. When the U.S. Air Force provides a reconnaissance capability in support of stability operations, U.S. Army MIBARS units will be provided to process and interpret Air Force imagery of interest to the host country and U.S. Army elements incountry.

127. Development of Interpretation Capabilities

In order to obtain the greatest value from imagery, interpreters are oriented toward a specific area of stability operations. Maximum use must be made of comparative imagery coverage so that over a period of time the interpreter "sees" on the imagery the same subtle changes that the aerial observer sees when flying over the same terrain day after day. All other sources of germane background information on the area, its people, and the way they live, are furnished the interpreter to help him better understand those things he must

identify and interpret. Maximum assistance must be made of host country military and civilian personnel, and in-country U.S. agencies that have background and experience on-the-ground in the areas of interest, to identify and interpret new or unusual items discovered on imagery. Imagery interpretation sections develop their own area-oriented imagery interpretation keys for newly discovered items to aid future identification, and to assist the indoctrination and training of newly assigned interpreters.

128. Phases of Interpretation Support

a. During early phases of insurgency, the interpreters' efforts are directed primarily to acquiring and cataloguing initial record imagery, and assembling the basic data and reference material and maps required for in-country use. This is the best time to initiate terrain and trafficability studies, and border surveillance. When possible, out-of-country coverage should also be secured and evaluated. Support should be furnished military and civilian activities in internal development and relocation operations by making specialized studies of these areas. Localized imagery interpretation keys are started at this time. Basic studies, map supplements, and imagery libraries are accumulated and interpreters are intensively trained for incountry requirements which must be accomplished at this time.

b. During tactical stability operations, imagery interpreters use comparative cover for interpretative studies. This requires a well stocked and catalogued imagery library. Comparisons are not only made between results obtained from similar type sensors at different times, but also between results obtained from different type sensors in both different and relatively the same time frame. Early in the insurgency the interpreter normally does not find concrete, direct evidence of insurgent activities on his imagery. He should, however, find a buildup of indirect indicators discussed in paragraph 121. Target surveillance folders containing continually updated intelligence information about insurgent activity in specific geographical areas are compiled. The initiation by the insurgents of more conventional tactical

operations make possible the increased use and reliability of IR and SLAR sensors. Enemy activity is identified from similarities to, rather than difference from, conventional war-

fare activity. At this time, the imagery interpreter effort converts to the more conventional aspects discussed in previous chapters.

1. Situation

- a. Enemy. Annex A (Intelligence) to OPORD 6.
- b. Friendly Forces. 373 Tactical Reconnaissance Wing, Ninth Tactical Air Force supports Thirtieth Army.

2. Mission

Reconnaissance elements of Ninth Tactical Air Force supports Thirtieth Army with 60 day, 15 night, and 4 electronic sorties per day from 170600 to 231800 May.

3. Execution

- a. Concept. Maximum use will be made of Army aircraft for visual, photo, and electronic missions. TAF reconnaissance will be used for photo and visual missions beyond organic capabilities. Target program to receive priority of support. Priority of Support: Army artillery, 3 Corps, 1 Corps, 2 Corps.

- b. Immediate Missions. Request via air request net as required. Use TAB A (Routes) TAB B (Areas), and TAB C (Point) overlays for visual requests.

- c. Preplanned Missions. Thirteenth Army SOP.

- d. 205th MI Bn (ARS). Plot all TAF photography, furnish daily master cover traces to army, corps, division; perform immediate interpretation of imagery flown in support of Army; conduct three flights daily between TAF recon bases, MI Bn (ARS), corps, divisions; other tasks as approved this HQ.

- e. Imagery Interpretation Responsibilities.

- (1) Divisions. All imagery produced organically; TAF imagery as requested.

- (2) Corps. Same as division.

4. Administration

- a. Distribution of imagery—Thirtieth Army SOP.
- b. Procedures for submission of mission requests—SOP.
- c. Other Imagery. Negatives of all photo, SLAR, and IR imagery produced at corps and division forwarded to this headquarters only on direction.

5. Command and Signal

- a. Army Command Net to be used for submission of preplanned requests only.
- b. Divisions monitor MIBARS Operations Net if possible.
- c. All units having capability monitor TAF in-flight report net.
- d. Base plan index, frequencies, and call signs—current SOI.

Acknowledge.

EXPLANATORY NOTES

SECTION I. TO BE USED BY ANY ARMY/AIR FORCE UNIT REQUESTING AIR RECONNAISSANCE.

- L. ORIGINATOR'S REQUEST NUMBER: EACH REQUEST WILL BE GIVEN A 3 PART REQUEST NUMBER. THE PREFIX WILL BE THE NUMERICAL OR LETTER DESIGNATION OF THE REQUESTER. SECOND PART IS THE RECONNAISSANCE REQUEST NUMBER OF THE DAY STARTING WITH 1 AND INCREASING CONSECUTIVELY THROUGHOUT THE DAY. THE SUFFIX WILL BE THE DATE THE MISSION IS TO BE PERFORMED, THE DATE THE MISSION IS FLOWN, EXAMPLE: 45-3-10 THE 3RD RECCE REQUEST BY THE 45TH INFANTRY DIVISION OF THE 10TH OF THE MONTH.
- M. TYPE OF RECONNAISSANCE: FOR EXAMPLE: VISUAL, ELECTRONIC, WEATHER, FIRE CONTROL OR PHOTOGRAPHIC RECONNAISSANCE (VERTICAL, OBLIQUE, IR, SLAR OR REPRINT PHOTOGRAPHY). THIS PARAGRAPH SHOULD BE LEFT BLANK UNLESS IT IS UNDERSTOOD FULLY WHAT THE SELECTED TYPE OF RECONNAISSANCE CAN ACCOMPLISH.
- N. NATIONAL MAP SERIES AND SHEET NUMBER: OWING TO THE LARGE VARIETY OF MAPS USED, BOTH IN TRAINING AND OPERATION BY NATIONS, THESE DETAILS MUST BE GIVEN IN FULL.
- O. DESCRIPTION OF TARGET AND LOCATION: TO INSURE THAT THE RECIPIENT OF THE REQUEST UNDERSTANDS THE REQUIREMENTS, IT IS NECESSARY TO GIVE AN EXACT LOCATION, E G, RAILWAY BRIDGE 775386. IN THE CASE OF OBLIQUE, THE NEAR BOUNDRY OF THE AREA TO BE PHOTOGRAPHED WILL BE GIVEN. ROUTE AND AREA BOUNDRIES WILL BE GIVEN FOR ROUTE OR AREA RECDNNAISSANCE.
- P. OBJECT OF THE REQUEST AND RESULTS DESIRED: IT IS IMPORTANT THAT THE EXACT PURPOSE OF THE REQUEST IS STATED IN ORDER THAT THE MOST SATISFACTORY RESULTS MAY BE OBTAINED.
- Q. PHOTO SCALE OR LIMITS ACCEPTABLE: WHENEVER POSSIBLE, THIS HEADING SHOULD BE FILLED IN ON THE ADVICE OF AN IMAGERY INTERPRETER. THE SCALE SHOULD BE QUOTED IN FIGURES, E G., 1/10000.
- R. NUMBER OF PRINTS, PLOTS, OR REPORTS REQUIRED: THIS SHOULD NEVER EXCEED THE NUMBER ACTUALLY REQUIRED. IF AN IMAGERY INTERPRETATION REPORT WILL SUFFICE, PRINTS SHOULD NOT BE ORDERED.
- S. DELIVERY ADDRESS, DATE, TIME: STATE CLEARLY WHERE THE PRINTS, PLOTS, OR REPORTS ARE TO BE DELIVERED AND THE TIME AND DATE ON WHICH THEY ARE REQUIRED. IF THERE IS NO HASTE, AS MUCH TIME AS POSSIBLE SHOULD BE GIVEN FOR FINAL DELIVERY SO AS TO ALLOW REQUESTS OF A MORE URGENT NATURE TO BE GIVEN PRIORITY.
- T. LATEST ACCEPTABLE TIME AND DATE: THE DATE OR TIME AFTER WHICH THE PRINTS, PLOTS, OR REPORTS ARE NOT LONGER REQUIRED. IF DELIVERY CANNOT BE MADE BY THE DATE STATED, THE REQUEST WILL BE CANCELED
- U. SPECIAL INSTRUCTIONS: THE DEGREE OF URGENCY, OR WHEN MAKING MORE THAN ONE REQUEST, THE DEGREE OF PRIORITY, AND THE SECURITY CLASSIFICATION OF THE MATERIAL REQUESTED. GIVE ANY INSTRUCTIONS OR INFORMATION NOT ALREADY PROVIDED, THAT WILL AID THE PLANNING, OR SUCCESSFUL ACCOMPLISHMENT OF THE MISSION, NAME A TELEPHONE NUMBER OF CONTACT OFFICER AND DESIRED TIME OVER TARGET IF APPLICABLE.

SECTION II. COMPLETED BY ARMY ACTION AGENCY AT ECHELON OF COMMAND ABOVE REQUESTING AGENCY.

- ITEM 1: INDICATE UNIT, DATE, TIME.
ITEM 2, 4, 6, 7, 8: INDICATE INITIAL, DATE, TIME.

SECTION III. COMPLETED BY AIR FORCE ACTION RECONNAISSANCE SECTION.

- ITEM 1: INDICATE UNIT, DATE, TIME. ITEM 2, 3, 5: INDICATE INITIALS, DATE, AND TIME.

SECTION IV. ITEM 3: AIRCRAFT CALL SIGN OR NUMBER. ITEM 6: AGENCY CONTROLLING MISSION.

- ITEM 7: TO INDICATE METHOD WHICH MISSION DATA (SECTION I) WILL BE TRANSMITTED TO THE ACCOMPLISHING UNIT, I.E., FRAG ORDER OR "IMMEDIATE REQUEST".
ITEM 8: SHOW INITIAL DATE AND TIME.

APPENDIX E

MINIMUM SCALES FOR INTERPRETATION AND IDENTIFICATION

1. This table is designed to indicate minimum acceptable photographic scales for interpretation purposes. These minimum scales are the conclusions of a qualified panel of interpreters. It is not expected that they will be valid for every situation, or that they will be in complete accord with the opinions or experience of all who refer to them. They will, however, serve as a *guide* to the minimum scales at which object-images can be identified and analyzed. The many variables in equipment capabilities, atmospheric conditions, and film processing which affect an aerial photograph will tend to alter these scales. These scales are based on average quality photography. Improvements in such factors as image-motion compensation, film resolution, optics, and camera mount vibration, will permit the use of smaller scales.

2. Column I indicates the minimum scale required for recognition of an object class (e.g., motor vehicle, artillery piece, multiengine aircraft, etc.). Column II indicates the minimum scale necessary for detailed analysis of specific objects within an object class (e.g., to distinguish 2½-ton trucks from 5-ton trucks; 105mm Howitzer from a 155mm Howitzer). The scales in column II are presented for guidance of aerial surveillance and reconnaissance personnel in planning missions designed to photograph specific installations for detailed technical analysis, while those in column I are the minimum scales for normal intelligence requirements. All scales refer to vertical stereo photo coverage. Low-level oblique photography or continuous-strip photograph, when indicated, may also prove extremely helpful in conducting detailed analysis.

Subject	Breakdown	I Minimum scale identification	II Minimum scale technical analysis
Industry -----	Industries which lend themselves to interpretation; e.g., coke, iron, and steel, petroleum, aluminum, etc.		
	(Typical) -----	1/30,000 -----	1/12,000.
	(Atypical) ----- (Petroleum and chemical plants require 1/6,000 for technical analysis.)	1/15,000 -----	1/8,000.
	Industries which do not lend themselves to interpretation; e.g., ball-bearing, instrument, electronics, etc.	1/10,000 -----	1/6,000 & low-level oblique continuous strip.
Defenses -----	Costal defenses guns -----	1/20,000 -----	1/5,000 & low-level oblique.
	Heavy AA -----	1/15,000 -----	1/3,000 & low-level oblique.
	Light AA -----	1/10,000 -----	1/2,000 & low-level oblique.
Artillery -----	All types -----	1/10,000 -----	1/2,000 & low-level oblique.
Vehicles -----	Motor vehicles -----	1/10,000 -----	1/2,000.
Transportation -----	Rail -----	1/30,000 -----	1/8,000.

Subject	Breakdown	I Minimum scale identification	II Minimum scale technical analysis
	Road ----- (Reliable road surface conditions cannot be given from aerial photo- graphy.)	1/30,000 -----	1/5,000.
	Inland waterways -----	1/30,000 -----	1/10,000.
	Bridges (over 100') -----	1/30,000 -----	1/10,000 oblique.
Utilities -----	Sewage -----	1/20,000 -----	1/10,000.
	Water purification -----	1/20,000 -----	1/10,000.
	Gas plants -----	1/20,000 -----	1/8,000.
	Municipal thermal ----- powerplant (typical)	1/30,000 -----	1/10,000.
	Industrial thermal ----- powerplant (typical)	1/15,000 -----	1/8,000.
	Central heating plant ----- (typical)	1/15,000 -----	1/6,000.
	Hydroelectric powerplant -----	1/30,000 -----	1/10,000.
	Powerlines (to trace) -----		1/6,000.
Terrain -----	Major landforms -----	No limit -----	1/20,000.
	Minor landforms -----	1/20,000 -----	1/8,000.
Vegetation -----	(Scales given are applicable to op- timum season only.) -----	1/20,000 -----	1/8,000 & low-level oblique, continuous-strip.
Shipping -----	Naval vessels—BB, CV, CA, CL (or units larger than DD) -----	1/25,000 -----	1/12,000.
	DD and minor combatant craft -----	1/15,000 -----	1/7,000.
	SS -----	1/25,000 -----	1/5,000 & low-level oblique.
	Merchant vessels: Units above 200' -----	1/25,000 -----	1/12,000.
	Units below 200' -----	1/15,000 -----	1/5,000.
Shipping facilities -----	Ports -----	1/25,000 -----	1/12,000.
	Docking facilities (piers, wharves, etc.) -----	1/20,000 -----	1/8,000.
	Services (cranes, wharf trackage, etc.) -----	1/12,000 -----	1/6,000.
Electronics -----	Radar: Fixed -----	1/10,000 -----	1/5,000.
	Mobile -----	1/8,000 -----	1/5,000.
	Fire control -----	1/5,000 -----	1/2,000.
	Communications: Lattice masts -----	1/15,000 -----	1/8,000.
	Stick masts -----	1/10,000 -----	1/5,000.
	D/F: Open adcock -----	1/18,000 -----	1/11,000.
	Portable or unusual types -----	1/8,000 -----	1/3,000.
	Navigation aids -----	1/18,000 -----	1/11,000.
Airports -----	Major (with facilities and surfaced landing area) -----	No limit -----	1/10,000.
	Auxiliary (surfaced landing area— no facilities)	1/30,000 -----	1/10,000.
	Auxiliary (unsurfaced landing area —no facilities)	1/10,000 -----	1/10,000.
Aircraft -----	Wing span: Under 40 ft -----	1/10,000 -----	1/2,000.
	40 to 60 ft -----	1/12,000 -----	1/3,000.
	60 to 100 ft -----	1/15,000 -----	1/4,000.
	over 100 ft -----	1/20,000 -----	1/5,000.

Subject	Breakdown	I Minimum scale identification	II Minimum scale technical analysis
Personnel -----	Personnel activity -----	Unknown -----	1/5,000 comparative cover essential. Low-level oblique. Continuous-strip (along travel routes including trails).
	Individual personnel -----	Unknown -----	
Structures -----	Structural analysis -----	1/12,500	1/1,000 & low-level oblique continuous-strip.
	Urban area analysis -----	1/12,500	
Photogrammetry --	Tri-met (for air navigation charts) -	1/60,000	
	Vertical (for mapping) -----	1/40,000	
	Supplemental (for air navigation charts and mapping) -----	1/20,000	

APPENDIX F

**NATO STANDARDIZATION AGREEMENT (STANAG 3189,
EDITION NO. 2—TITLING OF AIR RECONNAISSANCE,
AIR SURVEY, AND MAPPING PHOTOGRAPHY**

ANNEX A TO DETAILS OF AGREEMENT OF
STANAG 3189

(Edition No. 2)

INSTRUCTIONS FOR TITLING

GENERAL

1. The information detailed at paragraph 2 below, shall be titled on each end of each roll of air reconnaissance, air survey, and mapping photography, immediately before the first negative, and immediately after the last negative. This information shall include complete details of each run over of each separate target. The different items shall be arranged in the order shown. An example is given at paragraph 9 of this annex, and an explanation of each item in paragraph 2 is given at Annex 'B'.

TITLING SEQUENCE

- 2. + 1 Negative Number
- + 2 Camera Position (depression angle)
- + 3 Taking Unit
- + 4 Service
- + 5 Sortie/mission number
- + 6 Date (followed by a double hyphen (=))
- + 7 Time Group and Zone letter
- + 8 Focal Length
- + 9 Altitude
- + +10 Kind of Photography
- 11 Geographical Coordinates
- 12 Descriptive Title
- 13 Projective Number
- 14-19 Survey and Mapping Data, if required
- 20 etc. Additional Data, if required

Last Item: Security Classification

3. Items 1 to 6 inclusive shall form the negative/frame reference and shall be followed by a double hyphen (=). When operational factors prevent addition of the full titling data, the following absolute minimums will apply: Frame No.

Sortie/Mission No.

Date Time Group (Z) DTG(Z)

4. The starred items 1 to 9 inclusive shall be the minimum titling on each reconnaissance photograph. The double-starred item 10 shall appear on each survey and mapping negative, accompanied by acceptable electronic positioning data.

5. The appropriate security classification shall be shown on all material produced from the original roll of film.

6. If additional data must be inserted, it shall immediately precede the security classification which shall be the last item listed.

7. All titling shall be permanently marked in clearly legible capital letters, in such a position as to obscure the minimum of detail.

TITLING OF AIR SURVEY AND MAPPING PHOTOGRAPHY

8. The following information shall be titled on each end of each roll of air survey and mapping photography:

14. Camera Type and Serial Number.

15. Cone Serial Number.

16. Lens Type and Serial Number.

17. Magazine Type and Serial Number.

18. Type and Manufacturer of Photographic Film, and Type of Photographic Filter Used.

19. Mean terrain elevation above M.S.L. (Mean Sea Level).

EXAMPLE (For Titling of Air Reconnaissance Photography)

9. 121 F21 408 (R) RCAF 109 15 JUN 56 = 1630Z 36IN 12,000FT
4032N7607W TORONTO ATC56-1 SECRET

ANNEX B TO THE DETAILS OF AGREEMENT OF
STANAG 3189
(Edition No. 2)

EXPLANATION OF ITEMS USED FOR TITLING
(See EXAMPLE at Para 9 of Annex A)

1. Item No. 1 (Negative Number) "121"—denotes the 121st exposure of a consecutive sequence of exposures. Exposures from each magazine shall be numbered consecutively. If more than one magazine of a single camera is exposed on a mission or sortie, the exposures shall be numbered consecutively from exposure one (1) of the first magazine to the last exposure of the last magazine. Simultaneous exposures on trimetrogen, split vertical and convergent installations shall have their adjoining exposures matched and numbered identically.

2. Item No. 2 (Camera Position) "F21"—The following symbols shall be used to indicate camera position. Cameras will be numbered from port to starboard relative to the position photographed on the ground along the line of flight.

a. V-Vertical—The single letter V shall indicate a single vertical installation of one camera not tilted more than 5° from the vertical. Note: To indicate the first of more than one vertical, the symbol V1 shall be used, and V2 to indicate the second vertical. The cameras shall be numbered from nose to tail and where two are side by side, the left or port camera shall be numbered first.

b. F-Fan—The single letter F shall indicate a fan of two or more cameras. The F shall be followed by two digits; the first to indicate the number of cameras in the fan; the second to indicate the camera number.

e.g., A split fan—F21, F22
3 camera fan—F31, F32, F33
5 camera fan—F51, F52, F53, F54, F55

NOTE: When more than one fan is installed, the letter F shall be preceded by the number of the fan, these being numbered from nose to tail.

e.g., First fan—1F31, 1F32, 1F33
Second fan—2F21, 2F22
Third fan—3F51, 3F52, 3F53, 3F54, 3F55

c. C-Convergent Camera Installation—The single letter C shall indicate two cameras, installed in separate mounts, in the same mount, or 2 cones in the same camera body, the photography from which is used as a unit for mapping purposes. Normally, the cameras shall be disposed so that their principal plane is in the direction of flight with one camera pointing forward and the other rearward. The C shall be followed by a single digit; 1 to indicate the forward looking camera and 2 to indicate the rearward looking camera.

e.g., C1, C2

d. Oblique

P—Port (left)—A port facing oblique camera

S—Starboard (right)—A starboard facing oblique camera

N—Nose—A forward facing oblique camera

T—Tail—A rear facing oblique camera

H—Hand held

Cameras in multiple oblique installations will be designated by the letter P1, P2, etc., (Port), S1, S2, etc., (starboard) numbered from front to rear; N1, N2, etc., (Nose) T1, T2, etc., (Tail) numbered from port to starboard.

- e. Depression Angle—When oblique photography is titled, the depression angle in degrees measured from the horizontal plane of the aircraft shall be noted, between brackets, immediately following the camera position. (Not applicable for hand held obliques.)
- f. When cameras with an odd number of mirrors are used, the letter "M" shall be inserted immediately after the camera position, to indicate that the film must be reversed when printing. This is only to be shown with the titling information at the beginning and end of a roll.

3. Item No. 3 (Taking Unit) "408(R)"—denotes No. 408 Reconnaissance Squadron. Units shall utilize their official identifying symbol to identify their particular unit. The squadron detachment letter or number shall follow the squadron number. Where a letter is used, the letter shall be separated from the "Service" symbol by a single hyphen, e.g., "58A-DAF." When a number is used, it shall be separated from the squadron number by a single hyphen, e.g., "58-15 USAR."

4. Item No. 4 (Service) "RCAF"—denotes photographs made by the Royal Canadian Air Force. Other Services shall utilize appropriate symbols.

5. Item No. 5 (Sortie or Mission Number) "109"

6. Item No. 6 (Date) "15 JUN 56"—denotes the date photography is accomplished in the immediate area photographed.

7. Item No. 7 (Time Group and Zone letter) "1630Z."—Greenwich Mean time (Z) shall be used in every case.

8. Item No. 8 (Focal Length) "36IN" (Focal length of lens in inches (IN) or Centimetres (CM)—denotes equivalent focal length of lens indicated in inches or centimetres, except that all photography produced by calibrated cameras shall show the focal length in millimetres to the number of significant figures available data provides. Calibrated focal length shall be preceded by the letter C, when the certificate of calibration is current, e.g., "C153.52MM" (Calibrated focal length of lens in Millimetres (MM)).

9. Item No. 9 (Altitude) "1200FT"—denotes altitude above Mean Sea Level in feet (FT) or metres (M).

10. Item No. 10 (Kind of Photography)—The following symbols shall be used to indicate the kind of photography, other than reconnaissance:—

R—Infra-red

C—Charting

S—Survey and mapping (1st or highest order of accuracy)

C—Survey and mapping (2nd order of accuracy or below—Charting)

*SH—Survey and mapping horizontally controlled electronically

*SV—Survey and mapping vertically controlled electronically

*SHV—Survey and mapping horizontally and vertically controlled electronically

H—Historical

X—Experimental

*Note. The appropriate electronic positioning data symbol shall be placed on each Survey and Mapping negative that is acceptable controlled, as determined by the taking unit.

11. Item No. 11 (Geographical Coordinates—“4032N7607W.” Coordinates given shall apply to the centre of the photograph and be recorded to the nearest minute of latitude and longitude (based on Greenwich). The coordinates listed above indicate the geographic location of the first exposure of the roll or run used to photograph the target (Toronto). Similarly, the coordinates shall be indicated for the last exposure of a roll or the last exposure of a run over each separate target. When coordinates are recorded on each individual negative or print, they shall always represent the centre of the negative or print. If other coordinate systems are used, this fact shall be clearly stated.

12. Item No. 12 (Descriptive Title) “Toronto”—denotes the approximate place or subject of the photograph.

13. Item No. 13 (Project Number, year assigned, code name) “ATC56-1”—denotes the year (1956) and the first project assigned by the highest echelon directing the project. In this instance, Air Transport Command, RCAF.

14. Last Item (Security Classification) “SECRET”—denotes the security classification assigned to the photography in accordance with existing regulations or directives.

APPENDIX G
DETAILS OF AGREEMENT (DofA)

METHOD OF DESCRIBING GROUND LOCATIONS, AREAS, AND BOUNDARIES

NATO—UNCLASSIFIED

Agreed English/French Texts.

STANAG 2029
(Edition No. 2)

DETAILS OF AGREEMENT (DofA)

METHOD OF DESCRIBING GROUND LOCATIONS, AREAS, AND BOUNDARIES AGREEMENT

1. The NATO Armed Forces agree to adopt the method of describing ground locations, areas, and boundaries described in the following paragraphs. They further agree that the method defined shall be used in all orders, instructions, and reports and in any other circumstances where such descriptions are required.

DESCRIPTION OF LOCATIONS, AREAS, AND BOUNDARIES

2. Use of Maps. In order to avoid confusion in the designation of place names when there are various editions of a map relating to the same area, the following will be shown at the top of the document:

- a. Map Series Number (and country or geographic area, if required).
- b. Sheet Number (and name, if required).
- c. Edition.
- d. Scale (if required).

Example: This information can be shown as follows:

Map series number	M 501 EUROPE
Sheet	NM 32-1 (ESSEN)
Edition	1—DMG.
Scale	1:250,000.

3. Security. The location of headquarters, units, dumps, and other installations will only be mentioned in a communication or document if this communication or document can be transmitted to the addressee by a method ensuring the appropriate security. Locations of headquarters, units, dumps, and other installations will not be included in addresses unless necessary to ensure correct delivery.

4. Names of Places.

- a. Names of places will be written in block capitals exactly as spelled on the maps in use. The addition of a grid reference will almost always be necessary. In this case, six figure grid references must

NATO—UNCLASSIFIED

NATO—UNCLASSIFIED

not be used when four figures are sufficient. In certain areas, for which mapping material does not allow the use of coordinates, latitude or longitude designations will be used instead.

- b. When a grid reference code is used, the names of places which it indicates must not be shown in clear in the same message.

5. Locations and Points on the Ground.

- a. Locations and points on the ground may be described either:
 - (1) by grid coordinates, or;
 - (2) by giving the distance and direction from a simple reference point; e.g., "Cross-roads 1000 yards (or 1000 metres) South-west of church tower of NAPIERVILLE (square 6235)".
- b. In written orders and reports, grid coordinates will always be used the first time the designation of a point or location is given. Thereafter, coordinates will be given only when such repetition ensures greater clarity.

6. Directions. A direction can be indicated either by two points or by angular measurement reading clockwise from a reference direction. In the latter case, directions will be given as from true, magnetic, or grid north and the type used will always be specified. The unit of angular measurement used; i.e., mils or degrees is normally specified, but may be omitted when there is no probability of misunderstanding.

7. Roads, Tracks, and Railways.

- a. Roads, tracks, and railways will be described by the names of places located on them. Care must be taken to name enough places to make sure that the right road can be identified. The word "road," "track," or "railway" will precede, not follow, the place names; e.g., "road LAPRAIRIE-DELSON," NOT "LAPRAIRIE-DELSON road."
- b. When movement is involved, the route will be designated by a sequence of points on the route named in the direction of movement. When no movement is involved, the sequence of points named will be from left to right or rear to front, assuming that the person designating the route is facing the enemy. Cardinal points may be added if required.

8. Boundaries. Boundaries will be designated by easily distinguishable terrain features in the sequence in which they occur on the ground. They will be described from rear to front during an advance, and from front to rear in defense and withdrawal. If generally parallel to the front; e.g., rear boundaries, they will be described from left to right, facing the enemy. Cardinal points may be added if required.

9. When describing boundaries between units and formations, the words "inclusive" or "exclusive" will be used. These words should be used before the place to which they refer. The description of a boundary will state specifically to which unit or formation an area or a point is inclusive or exclusive.

NATO—UNCLASSIFIED

NATO—UNCLASSIFIED

Example: 5 Brigade and 6 Brigade are advancing together. The inter-Brigade boundary will, therefore, be described from rear to front. The most concise way of listing the various references comprising the boundary is to link them with one of the units/formations concerned, thus:

Boundary (ies)	exclusive LAPRAIRIE	6134
<u>5 Brigade</u>	exclusive Cross Roads	621352
	inclusive Wood	624336
	exclusive Road	
	LAPRAIRIE-DELSON	6238

10. River Banks. River banks are described as right or left from the point of view of an observer facing downstream or, if this cannot be done, by using cardinal points.

11. Areas. An area will normally be described by taking the northermost point first and giving the remaining points in clockwise order.

12. Positions. Positions will be described from left to right and front to rear facing the enemy. To avoid confusion, cardinal points may be used to describe flanks, rather than "right" or "left".

IMPLEMENTATION OF THE AGREEMENT

13. This STANAG will be considered to have been implemented when the necessary orders/instructions to adopt the method described in this Agreement have been issued to the forces concerned.
